weathering from the cliffs above high water mark. But a certain amount of erosion is directly effected by the waves, especially on coasts liable to heavy seas. Most of this is accomplished at a very slow rate if the rocks affected are of a durable kind; and the wasting is carried out chiefly by the gradual enlargement of chinks, joints, fissures of any kind, or any zones of weakness in the rocks lying within reach of the waves. These weak places are gradually widened, the rocks are tunnelled into sea caverns, their roofs in time are blown off during some exceptionally violent gale, the sides of the whilom caverns in time are worn into sea stacks, these into skerries (only visible at low tide), and these skerries eventually into a shore platform, which is levelled off to the same elevation for great distances along the coast line. Chemical action also takes an important share in the work. For example, a basalt, containing, as it does, a ferromagnesian silicate and a lime soda felspar, will decompose on the land in such a manner that the felspar goes first and the ferromagnesian silicate last; but where the same rock is exposed to the chemical action of sea water the order of decomposition is reversed and the felspar may remain apparently unchanged after the rest of the rock has disappeared. It is now believed, with good reason, that the more energetic (but irregular) action of marine erosion is less effective in the long run than the quieter (but continuous) action of subaërial denudation.

Seal. (1) A piece of metal or stone (sometimes a gem) with a design or device engraved upon it; used for making an impression on some suitable substance such as wax. (2) The impression so obtained. *Cf.* SCARAB.

—— (*Eng.*) The slight projection of the edge of a steam valve over the edge of a part which it covers. This makes a steam-tight joint.

—— (*Plumb.*) The fluid which fills the trap or bend of a drainage pipe and so prevents the upward passage of gases; also termed a WATER SEAL. Water can flow downwards, but gases cannot rise past the bend unless the pressure exceed a certain value. *See* SIPHON TRAP.

Sealing. In general, closing up, making a joint, or securing by the attachment of some substance which must be broken before the sealed joint can be opened. Glass apparatus is sealed by fusing together the edges of an opening or tube. A meter or registering apparatus is "sealed" by the attachment of a leaden seal, impressed with some device, to any convenient place, in such a manner that access to the interior cannot be obtained without breaking the seal or cutting wires which pass through it.

Seam (*Eng.*) A long joint between two plates or in a pipe made by bending a plate. The term is usually (but not always) restricted to welded or brazed joints, as distinguished from those which are riveted.

—— (*Mining*). A bed or layer of coal; occasionally the term is applied to a stratum of some other rock.

Seamless Tubes. SOLID DRAWN TUBES (*q.v.*)

Seam Set (*Eng.*) The tool used for closing up the seams in a tube formed from sheet metal.

Searchlight. A powerful arc lamp, provided with optical means whereby its rays can be concentrated in a narrow beam, and with mechanical devices for directing this beam in any required direction.

Searing (*Pattern Making*). Smoothing the surface of a roughly made pattern by means of a hot iron; this process also serves to render the surface less liable to absorb moisture from the sand.

Sea Sand (*Foundry*). This is suitable for making cores (*q.v.*), but requires the admixture of a small amount of clay in order to make it bind or adhere.

Seascape (*Art*). A picture representing a marine view.

Seasoning (*Leather Manufac.*) In the tanyard this means bringing the leather to a proper state of moisture (damping or drying) previous to rolling. In the dyeing and finishing of light leather, skins, after dyeing and before glazing, are coated with a seasoning liquid, consisting in most cases of albumen in some form, either vegetable or animal, mixed with various dilutants.

—— (*Timber*). Drying out the sap from timber before use; it is effected either naturally by exposure to the air, or by means of hot air (artificial seasoning). In the latter method a great part of the sap may be removed by soaking the timber in water previous to the artificial drying.

Seasons (*Astron.*) The divisions of the year, determined by the position of the earth in regard to the sun. The earth in its orbital motion round the sun keeps its axis nearly parallel to itself; the poles of the earth vary in their presentation to the sun, hence the different conditions of spring, summer, autumn, and winter.

Seat *or* **Seating** (*Eng.*) (1) A base plate in general. (2) The structure on which the movable part of a valve rests.

Seat Earth (*Geol.*) Another name for FIRECLAY.

Seat Lug (*Cycles*). The lug (*see* CYCLES) through which the seat pillar passes.

Sea Wall (*Civil Eng.*) An upright or, more commonly, sloping wall of masonry, concrete, etc., intended to protect the land from erosion or inundation.

Sea Water. Sea water contains about 3·5 per cent. of dissolved salts, of which about 2·7 per cent. consists of common salt. A fairly typical analysis of sea water gives:

Sodium chloride . . .	2·64 per cent.
Potassium chloride . . .	·07 " "
Magnesium chloride . .	·31 " "
Magnesium sulphate . .	·21 " "
Calcium sulphate . . .	·13 " "

In addition to these substances, there may be small amounts of iodine and of various other mineral salts. The specific gravity is usually between 1·024 and 1·027. Sea water is used in marine boilers, due precautions being taken to prevent too large an accumulation of salt.

Sec (*Music*). Sharp, crisp; often placed over certain notes.

——, **Secant.** *See* TRIGONOMETRICAL RATIOS.

Secco (*Music*). Plain, unadorned. *See* RECITATIVE.

Secohm (*Elect.*) The term formerly applied to the HENRY or unit of inductance.

Secohmmeter (*Elect.*) An apparatus for measuring self-induction and mutual induction.

Second. *See* WEIGHTS AND MEASURES.

Second (*Music*). The interval contained between two notes next to each other in alphabetical order, as C to D, C to D♯. *See* INTERVALS.

Secondaries to a Circle. *See* SPHERE.

Secondary Alcohol (*Chem.*) *See* ALCOHOL.

Secondary Alcohols (*Chem.*) Alcohols of the formula

$$\begin{matrix}R\\R_1\end{matrix}\!\!>C<\!\!\begin{matrix}H\\OH\end{matrix}$$

where R and R_1 are radicals joined by carbon to the carbon of the CHOH group, and may be the same or different. Examples:

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>CHOH,\ \text{Isopropyl alcohol.}$$

$$\begin{matrix}CH_3\\C_2H_5\end{matrix}\!\!>CHOH,\ \begin{matrix}\text{Methylethyl carbinol.}\\\text{(2-Butanol)}\end{matrix}$$

The secondary alcohol group occurs in many important compounds; for example, in glycerine, $\begin{matrix}CH_2OH\\|\\CHOH\\|\\CH_2OH\end{matrix}$; in lactic acid, $\begin{matrix}CH_3\\|\\CHOH\\|\\COOH\end{matrix}$; in the sugars, in morphia, etc.

They may be prepared (1) from primary alcohols. *See* PROPYL ALCOHOLS. (2) By reduction of ketones. *See* KETONES. (3) From aldehydes by the action of zinc alkyls or magnesium alkyl iodides: *e.g.* with acetaldehyde and zinc methyl addition takes place—

$$\begin{matrix}CH_3\\|\\C\end{matrix}\!\!<\!\!\begin{matrix}O\\H\end{matrix} + Zn(CH_3)_2 = \begin{matrix}CH_3\\|\\C\end{matrix}\!\!<\!\!\begin{matrix}OZnCH_3\\CH_3\\H\end{matrix}$$

The compound so formed is decomposed by water —

$$\begin{matrix}CH_3\\|\\C\end{matrix}\!\!<\!\!\begin{matrix}OZnCH_3\\CH_3\\H\end{matrix} + HOH = \begin{matrix}CH_3\\|\\C\end{matrix}\!\!<\!\!\begin{matrix}OH\\CH_3\\H\end{matrix}$$
$$+ ZnO + CH_4.$$

(4) From formic esters by the zinc alkyls, using two molecular proportions of the latter. This is a particular case of method (3), for formic esters contain the aldehyde group—

$$\begin{matrix}H\\|\\C\\|\\OC_2H_5\end{matrix}\!\!<\!\!\begin{matrix}OZnCH_3\\CH_3\end{matrix} + Zn(CH_3)_2 = \begin{matrix}H\\|\\C\\|\\CH_3\end{matrix}\!\!<\!\!\begin{matrix}OZnCH_3\\CH_3\end{matrix} +$$
$$Zn\!<\!\!\begin{matrix}CH_3\\OC_2H_5\end{matrix}$$

The addition product is the same as in (3). The reactions of secondary alcohols with sodium, chlorides of phosphorus, acids, are in general like those of primary alcohols. On oxidisation they yield ketones (*q.v.*); thus isopropyl alcohol gives acetone and lactic acid gives pyruvic acid (*q.v.*) For a method of distinguishing secondary from primary and tertiary alcohols *see* NITROSO-COMPOUNDS.

Secondary Bases (*Chem.*) Compounds of the formula $\begin{matrix}R\\R_1\end{matrix}\!\!>NH$, where R and R_1 are radicals, which may be the same or different, attached to the nitrogen by carbon. For illustrations see the following compounds: DIETHYLAMINE, PIPERIDINE, CONINE.

Secondary Bows (*Meteorol.*) *See* RAINBOWS.

Secondary Cell *or* **Battery** (*Elect.*) *See* ACCUMULATORS.

Secondary Hydrocarbons (*Chem.*) A hydrocarbon containing at least one carbon atom united to three other carbon atoms, *e.g.* Isobutane—

$$CH_3CH<\!\!\begin{matrix}CH_3\\CH_3\end{matrix}$$

See PARAFFINS.

Secondary Rocks (*Geol.*) Usually understood to be the strata which in Europe were formed while Ammonites lived in the seas, and while the dominant forms of vertebrate life were reptiles of various kinds. The strata thus include all rocks of later date than the uppermost Carboniferous rocks on the one hand and the base of the oldest Eocene rocks on the other. *See* STRATA, TABLE OF.

Second Cut File (*Eng.*) A file with teeth next in order of coarseness to a SMOOTH CUT file (*q.v.*)

Secondo (*Music*). Second, as the second performer in a duet; the lower or bass part of a duet for one pianoforte. Seconda, 2ma or 2nd time, is often placed after a repeat to show that certain bars are to be substituted for those marked prima before the repeat. *See* PRIMO.

Second Tap (*Eng.*) *See* TAP.

Secret Dovetail (*Carp. and Join.*) A joint constructed so that the dovetails are hidden by a mitre. *See* DOVETAIL.

Secret Fixing (*Carp. and Join.*) The methods of fixing joinery so that the fixings cannot be seen.

Secret Nailing (*Carp. and Join.*) Nailing together the parts of a piece of work in such a way that the heads of the nails do not lie in the visible surface of the finished object. Thus flooring composed of narrow strips or blocks may be fixed down by nails driven obliquely through the edge (or vertical side) of one block, before the next block is laid in place.

Sectile (*Min.*) Capable of being cut by a knife, but not malleable; *e.g.* Steatite.

Section. (1) A cut across an object, the direction of the cut being stated, *e.g.* Cross, Horizontal, or Vertical Section. (2) A drawing of such a cut surface. (3) A distinct portion of a structure.

—— (*Typog. and Bind.*) (1) A distinct portion of a book: a sheet. *Cf.* SIGNATURE. (2) A subdivision of a chapter; hence the reference sign § used to denote such a division. *See* NOTES.

Sectional Area. The area of a section, especially of the cross section of an object.

Sectional Colours. Certain conventional colours are used in drawings to represent different materials, *e.g.* grey for cast iron, yellow for brass, etc.

Sectional Plan. A drawing showing the appearance which an object would present if it were cut through by a horizontal plane.

Sector. (1) The part of a circle lying between two radii and the portion of the circumference connecting them. The term is also applied to a similar

figure derived from other curves. (2) A form of divided scale used by draughtsmen. (3) An instrument for the measurement of angles. *See* ZENITH SECTOR.

Secular Changes (*Astron., Geol., etc.*) Changes which occur progressively throughout ages of time—*i.e.* in a vastly extended though indefinite period; *e.g.* movements of the earth's crust, or the gradual alterations in the value of the magnetic elements.

Sedan Chair. *See* CHAIR, SEDAN.

Sedilia (*Architect.*) The seats, usually three, which are frequently formed in the south wall of the chancel of churches and cathedrals. The singular of Sedilia, *Sedile*, is seldom used.

Sedimentary Rocks (*Geol.*) Strata deposited outside of the earth's crust directly or indirectly by the action of water, or of currents of air, or of ice. Rocks formed by volcanic action, properly so-called, are usually stratified, but they are excluded by the definition just given.

Seebeck Effect (*Elect.*) Thermo-electric phenomena (*q.v.*)

Seeding (*Chem. Tech.*) The separation of stearic and palmitic acids from liquid oleic acid by crystallisation in the manufacture of stearine. The fatty acids from the decomposed "rock" (*q.v.*) are run into shallow cooling pans arranged in stacks. The resultant slabs of granular solid acids and liquid oleic acid are known as SEPARATION CAKE.

Seggar (*Pot.*) A round, oval, or square box of burnt fireclay, varying in depth, in which clay wares are placed for the bisque oven, and bisque wares for the glost oven. In the latter case the seggars are glazed.

Seggar Clay (*Geol.*) Another name for FIRE-CLAY.

Segment. The part of a circle enclosed by an arc and a chord.

Segno (*Music*). The sign 𝄋. *See* AL SEGNO *and* DAL SEGNO.

Segregation Veins (*Geol.*) When an eruptive rock is cooling it necessarily contracts, and hence there is a tendency to the formation of fissures as the rock adapts itself to the space available. Some of the materials which consolidate later gradually ooze into these fissures, and eventually crystallise there. In an eruptive rock these segregation veins or Aplites, as they are now called, are always more acid in chemical composition than their enclosing rock.

Segue; Seguendo (*Music*). Follows: following. *Segue* is placed after one movement to indicate that the next follows on. *Attacca* is now used for the same purpose.

Seismograph. An instrument for recording (on a sheet of paper, smoked surface, etc.) the movements of the crust of the earth during an earthquake. The term is also applied to the traced or written record itself.

Seizing (*Eng.*) The fixing or jamming of a bearing which sometimes occurs when it becomes hot through insufficient lubrication.

Seizure (*Eng.*) Bearings, etc. *See* SEIZING.

Sekos (*Architect.*) The sanctuary in an ancient Egyptian temple.

Selenite (*Geol.*) A name applied to the clear varieties of GYPSUM (*q.v.*) Selenite occurs under geological conditions somewhat different from normal gypsum. It is quite commonly developed within clays, *e.g.* the London Clay or the Oxford Clay, probably as a result of the decomposition of pyrites and the recombination of the sulphuric acid thus formed with solution of carbonate of lime. But no selenite occurs in the chalk, though pyrites abounds in some parts of it.

Selenite (*Min.*) The transparent variety of GYPSUM (*q.v.*)

Selenium (*Chem.*) Se. Atomic weight, 79·2. (Also called Selenion.) A rare element closely resembling sulphur in its chemical behaviour, and belonging to the same group in the Periodic system. It is a solid having several allotropic forms. AMORPHOUS SELENIUM is a red powder obtained by reduction of selenious acid by sulphurous acid, stannous chloride, and other reducing agents; also by allowing a solution of selenium hydride to stand exposed to air. It is slightly soluble in carbon disulphide and benzene, and when allowed to stand under these solvents exposed to light it passes into the red crystalline form. Another amorphous form, known as vitreous selenium, is produced when melted selenium is rapidly cooled. CRYSTALLINE FORMS: A dark grey crystalline form with metallic lustre is obtained from either of the two preceding varieties by *gradually* heating them; at about 100° they pass into this form with evolution of heat, the temperature rising to 217°, which is the melting point of this variety. This variety is insoluble. The red crystalline form is obtained as above, and crystallises in two distinct forms—it changes on heating to the dark grey form. COLLOIDAL SELENIUM: Formed on reduction of very dilute solutions of selenious acid by sulphur dioxide or hydrazine hydrate; on dialysing the liquid a red solution showing blue fluorescence by reflected light is obtained; the solution may be boiled without change, but electrolytes precipitate red gelatinous selenium, which becomes black on heating. Selenium boils at 680°; below about 950° it contains complex molecules, probably Se_8; but at 950° and over the molecules consist of Se_2. In the vacuum of the kathode light it boils at 310° under the pressure of a 60 mm. column of its own vapour. Selenium is a bad conductor of electricity, but its resistance diminishes on exposure to light, the grey crystalline form being most sensitive; various physical applications have been made of this property. Selenium burns with a blue flame when heated in air forming the dioxide; in general its chemical behaviour resembles that of sulphur. Selenium occurs widely distributed, but always in small quantity; its two chief sources are the flue dust which is deposited in roasting sulphides such as selenium containing copper pyrites, and a deposit in the leaden chambers of the sulphuric acid manufacture when certain kinds of pyrites are burned. To obtain it from the latter, the deposit is washed and boiled with a concentrated solution of sodium sulphite. To the filtered liquid hydrochloric acid is added, which precipitates the selenium; the process is repeated till the selenium is pure. *Compounds:* Selenium hydride, H_2Se (Seleniuretted hydrogen) is a colourless gas; boils at −40°; smells like sulphuretted hydrogen at first, but has much more severe after-effects, irritating the mucous membrane and temporarily destroying the sense of smell; it is about as soluble in water as sulphuretted hydrogen, and like it gives precipitates with metals—selenides; decomposed by light. The gas is prepared

in a similar manner to sulphuretted hydrogen, namely, by heating the element in hydrogen; decomposing ferrous selenide with dilute hydrochloric acid; decomposing aluminium selenide with water. Selenious oxide, SeO_2, forms white needles, which sublime without melting, and dissolve in water, forming selenious acid. It is prepared by burning selenium in dry oxygen, or by the action of nitric acid on selenium, and repeated evaporation of the solution with water to obtain selenious acid, which gives the dioxide when heated in oxygen. Selenious acid, H_2SeO_3, crystallises in white prisms; when heated gives selenious oxide and water; soluble in water; the solution is easily reduced to the element (*see above*); oxidising agents convert it into selenic acid; forms both normal and acid selenites. The acid and its salts are poisons. Selenious acid is obtained as described under the oxide. Selenic acid, H_2SeO_4, crystallises in white prisms; melts at 58°; mixes with water with evolution of much heat; the solution behaves like sulphuric acid in most respects; the concentrated acid chars many organic substances when heated with them, while the dilute acid dissolves metals in an analogous manner to dilute sulphuric acid. Very concentrated selenic acid dissolves gold leaf, forming the dioxide and auric selenate, $Au_2(SeO_4)_3$. Heated with hydrochloric acid, selenious acid is formed with evolution of chlorine. The selenates resemble the sulphates except that they are decomposed by hydrochloric acid like selenic acid itself. Selenic acid is obtained by oxidising a solution of selenious acid with chlorine; or selenious acid is precipitated with silver nitrate, the precipitate washed, and oxidised with bromine and water; the solution of selenic acid is evaporated as far as possible on the water bath, then distilled in a vacuum till nothing more comes over at 180°. Selenium forms many organic compounds; special interest attaches to one of these, in which a selenium atom is united to four different monovalent groups, as it can be resolved into optically active components. Benzene sulphonic chloride and benzene react in presence of aluminium chloride to form diphenyl sulphone, which yields diphenyl diselenide when heated with sufficient selenium; the selenide yields methylphenylselenide with sodium and methyl iodide; this compound combines with bromacetic acid to form phenylmethylselenetine bromide—

$$C_6H_5SO_2Cl \xrightarrow[C_6H_6]{} (C_6H_5)_2SO_2 \xrightarrow[Se]{} C_6H_5Se.SeC_6H_5 \xrightarrow[CH_3I]{}$$

$$C_6H_5SeCH_3 \xrightarrow[CH_2BrCOOH]{} \begin{array}{c} CH_3 \\ C_6H_5 \end{array}\!\!>\!Se\!<\!\!\begin{array}{c} CH_2COOH \\ Br \end{array}$$

When this compound is precipitated with silver *d*-bromcamphorsulphonate, a product is obtained which can be separated by fractional crystallisation into dextro- and lævorotatory compounds.

Selenium (*Min.*) This element occurs native in cavities in the lavas of Vesuvius. It is of a dark brown or grey colour by reflected light, but red in thin pieces by transmitted light. The element also occurs in combination with sulphur and tellurium, and as selenide in several rare minerals. There is also one mineral which is a selenite, Chalcomenite.

Selenograph (*Astron.*) A picture of the surface of the moon, or some portion of it.

Selenography (*Astron.*) The study of the geography of the moon.

Self Acting Lathe (*Eng.*) This term is usually applied to a lathe in which both longitudinal and transverse motions can be given to the slide rest by means of a shaft fixed along the back of the bed. This longitudinal motion or feed is entirely independent of that used in screw cutting. The term "self acting" is, however, often applied to lathes which have the screw cutting mechanism only.

Self Centering Chuck (*Eng.*) A chuck with three (rarely two or four) jaws, which can be moved simultaneously in a radial direction across the face of the chuck, always remaining equidistant from the centre. A cylindrical object held in these jaws will always have its axis coincident with the axis of the chuck. The jaws are caused to move by some form of gearing, or by a spiral groove or scroll cut in a circular plate, each jaw having a projection which fits into the groove.

Self Delivery (*Foundry*). The formation of hollow parts of a casting without the use of cores, the actual hollow being formed on the pattern itself. The sand of the mould fills this hollow, and the necessity for a separately prepared core (*q.v.*) is obviated. Self delivery is only possible in a limited number of cases.

Self Exciting Dynamo (*Elect. Eng.*) A dynamo whose field magnets are excited by current produced by the machine itself, as distinguished from a SEPARATELY EXCITED MACHINE (*q.v.*)

Self Fluxing Ores (*Met.*) Applied to certain iron ores containing calcareous matter which serves as a FLUX (*q.v.*), so that the addition of lime to the furnace charge is not necessary.

Self Induction (*Elect.*) *See* INDUCTION, SELF.

Sellers' Screw Threads (*Eng.*) The American standard form of V-thread, having an angle of 60°; used in America instead of the Whitworth pattern. *See* SCREW THREADS.

Seltzer Water (*Chem.*) *See* WATER.

Selvedge *or* **Listing** (*Textile Manufac.*) The list or side threads of a fabric, usually composed of stronger threads than the main portion, so as to bear the increased friction and strain in the reed during the operation of weaving, and otherwise protect the real cloth. *See also* LIZIER.

Semaphore. A signal having a hinged lever arm, such as is used on railways and in the Navy. *See under* RAILWAYS.

Sémé *or* **Powdered** (*Her.*) A shield is described as *sémé* when covered with small charges scattered all over the surface. France ancient is *sémé* of *Fleur de lys*.

Semi-Beam *or* **Semi-Girder** (*Eng.*) A term sometimes applied to a CANTILEVER (*q.v.*)

Semibreve (*Music*). The name given to the standard note of measurement in modern music and to its equivalent rest. *See* NOTES *and* RESTS.

Semicarbazide (*Chem.*) $CO\!<\!\!\begin{array}{l} NH.NH_2 \\ NH_2 \end{array}$

(Aminourea). White prisms; melts at 96°; soluble in water, benzene, chloroform. Decomposes on keeping into hydrazine and hydrazodicarbonamide; it decomposes in the same way on heating.

$$2H_2N.NH.CO.NH_2 = H_2N.CO.NH.NH.CONH_2 + H_2N.NH_2$$

With nitrous acid it gives azoimidocarbonamide:

$$\left\{\begin{array}{r} H_2NCONH.NH_2 + ON.OH = H_2N.CO.NH.N:NOH + H_2O \\ H_2NCONHN:NOH = H_2N.CO.N\!<\!\!\begin{array}{c} N \\ \| \\ N \end{array} + H_2O \end{array}\right\}$$

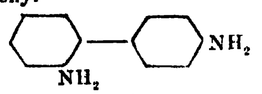
It is a very useful reagent for aldehydes and ketones, especially when these do not form well crystallised

oximes or hydrazones. To use it for this purpose the hydrochloride is employed (occasionally the sulphate must be used as with ionone); this salt is dissolved in a little water and its equivalent of an alcoholic solution of potassium acetate added; then the aldehyde or ketone added and more alcohol to complete the solution. The mixture is warmed, if necessary (*e.g.* with sugars and quinones); the time required varies from a few minutes to days. The products from aldehydes are called SEMICARBAZIDES, those from ketones SEMICARBAZONES. Semicarbazide is prepared by heating molecular proportions of urea and hydrazine hydrate in a tube at 100° for 20 hours; the contents are washed out with water and evaporated as far as possible on a water-bath; the viscous liquid so obtained crystallises on standing in a desiccator over sulphuric acid; the crystals are pressed on a porous plate and recrystallised from absolute alcohol. The hydrochloride is prepared by neutralising a solution of 13 grams of hydrazine sulphate in 100 cc. water with 5·5 grams dry sodium carbonate; when cool 8·8 grams of potassium cyanate are added and left 12 hours. The liquid is acidified with sulphuric acid and filtered from hydrazidodicarbonamide; the filtrate is shaken with benzaldehyde, when a precipitate of benzalsemicarbazide is obtained; this is filtered and washed with ether; then decomposed by cautious warming on the water-bath with concentrated hydrochloric acid (20 grams require 40 grams acid), and water added till all just dissolves. The warm liquid is shaken with benzene to remove benzaldehyde. The aqueous solution deposits the hydrochloride on cooling in small needles which form beautiful prisms when recrystallised from dilute alcohol; from the mother liquor more can be obtained by precipitation with benzaldehyde, etc. It can also be obtained by the electrolytic reduction of nitrourea in ammonium chloride solution, using wrought iron electrodes (70 sq. cm. of each immersed) and a current of 2 ampères for 20 hours; the cell stands in cold water. The product is precipitated with benzaldehyde, etc. The sulphate is made by decomposing acetone semicarbazone in alcoholic solution with the calculated quantity of sulphuric acid, when it separates out and is washed with alcohol.

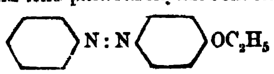
Semidemisemiquaver (*Music*). The name given to the note which is one sixty-fourth part of a semibreve, and to its equivalent rest. Also called a hemidemisemiquaver, *i.e.* a half-half-half-quaver. *See* NOTES *and* RESTS.

Semi-Diameter (*Astron.*) The distance from the centre to the circumference. Generally applied to the discs of the sun, planets, etc., or orbits.

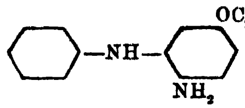
Semidine Transformation (*Chem.*) When azobenzene is reduced it yields hydrazobenzene, and the latter, when treated with an acid, yields benzidine (*see* HYDRAZOBENZENE). Besides the benzidine there is formed a smaller quantity of orthoparadiamidodiphenyl



In a compound like paraethoxyazobenzene

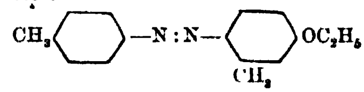


where the para position is occupied, a benzidine transformation cannot occur; reduction to the hydrazo-compound occurs, a little aniline and paraamidophenetole are formed; but the two principal products of the reaction are



and

These compounds are called SEMIDINES: the first is an orthosemidine and the second a parasemidine, and the reaction is known as the semidine transformation. With methylparaethoxyazobenzene the course taken by the semidine transformation depends on the position of the methyl group; when the methyl group is in any meta position to the azo group the reaction is similar to that which occurs when no methyl group is present and ortho-semidines are the chief product: when the methyl group is in an ortho position to the azo group parasemidines are the chief product. When both para positions and one ortho position are filled as in paratolueneazometacresetole



so that the parasemidine transformation cannot occur, then a little orthosemidine compound is formed, but the chief action is reduction to paratoluidine and ethoxyorthotoluidine. Now, as the orthosemidine transformation always occurs by the replacement of a hydrogen atom in the nucleus containing the ethoxy group, it is inferred that when a methyl group occupies an ortho position the space occupied by this group is a hindrance to another group entering an ortho position, and thus the parasemidine transformation occurs. (*See* Scholtz's "Raumerfüllung der Atomgruppen.")

Semi-Permeable Membranes *or* **Partitions** (*Chem.*) Membranes which, when they separate two solutions in the same solvent of different osmotic pressure, permit of the passage of the solvent, but not of the passage of the dissolved substance, from the solution of less osmotic pressure to that of greater osmotic pressure. The best semi-permeable membranes are the cell walls of certain vegetable and animal cells, such as the cells from the epidermis over the midrib of the violet or under side of the leaf of *Tradescantia discolor*, or the exterior cells of the spathe of *Curcuma rubicaulis*, or red blood corpuscles. The best artificial semi-permeable membrane is copper ferrocyanide. The action of the vegetable cells must be observed under the microscope. The action of the red blood corpuscles can be observed in a test tube. 0·5 cc. of defibrinated ox blood is put in a test tube containing about 20 cc. of a solution of potassium nitrate; if the strength of the nitrate is 1·04 per cent. or over, then on shaking and allowing to stand the corpuscles settle to the bottom of the tube, and the liquid above them is clear and nearly colourless; if the solution of nitrate is 0·96 per cent. or under, the clear layer standing over the deposited corpuscles shows a faint red colour—water with minute traces of hæmoglobin have escaped through the walls of the corpuscles. The artificial membrane is made by thoroughly soaking a porous pot in water, then in 3 per cent. solution of copper sulphate; after rinsing with water and drying with filter paper, a

3 per cent. solution of potassium ferrocyanide is poured in, and the pot stood in a solution of copper sulphate (3 per cent.) for a day or two; the latter process is repeated with the pot closed. To use the cell, a glass tube is sealed into it by sealing wax, the apparatus filled with the aqueous solution to be tested, the glass tube connected to a mercury manometer, and the porous pot stood in water. The copper ferrocyanide film deposited in the material of the porous cell will only hold for a few substances, such as the sugars and urea; for most substances it is useless for purposes of measurement. *See* OSMOTIC PRESSURE.

Semi-Porcelain (True). A class of ware coming between porcelain and earthenware in its characteristics. It is a "soft paste," more resonant than earthenware, absolutely non-absorbent, but only slightly translucent even when made very thin. Many so-called "semi-porcelains" are only "earthenwares." *See* POTTERY AND PORCELAIN.

Semiquaver (*Music*). The name given to the note which is one-sixteenth part of a semibreve, and to its equivalent rest. *See* NOTES *and* RESTS.

Semitone (*Music*). One-half of a tone. The semitone is the smallest interval recognised in practical music, and is that contained by two notes of the pianoforte next to each other, as from C to the black note next above, or from C to the white note next below it. Semitones are of two kinds: (1) Diatonic, when the notes are next to each other alphabetically, as E F, G A♭, *i.e.* when they are both contained in one diatonic scale. (2) Chromatic, when the notes are the same alphabetically, but altered by ♯, ♭, or ♮, as F F♯, G♭ G♮. *See* INTERVALS *and* SCALES.

Semplice (*Music*). Simple. *Semplicemente*, simply.

Sempre (*Music*). Always, as *sempre legato*, always (continued) smoothly and connected.

Senarmontite (*Min.*) A rare form of oxide of antimony, Sb_2O_3; cubic, in octahedrons; also in capillary masses. Colourless or grey. From Algeria and Hungary. *Cf.* VALENTINITE.

Sendal (*Archæol.*) A silken material of light texture, formerly used for banners and for dress.

Sender (*Elect.*) The instrument employed in transmitting a telegraphic message.

Seneca Oil. A synonym for Petroleum (*q.v.*)

Senega Root (*Botany*). The dried root of *Polygala senega* (order, *Polygalaceæ*) is used in medicine. It is imported from the United States.

Senna (*Botany*). *Cassia acutifolia* yields ALEXANDRIAN SENNA; *C. obovata* yields ITALIAN SENNA; and *C. angustifolia* the EAST INDIAN variety (order, *Leguminosæ*). The drug, which is used as a laxative, consists of the dried leaflets.

Sensibile (*Music*). Expressive.

Sensibility of a Galvanometer (*Elect.*) This term is used in various senses: *e.g.* (1) The deflection produced by a given current; (2) The current, or the reciprocal of the current, required to produce a given deflection.

Sensible Heat. Heat which can be perceived by the senses, owing to a change in temperature, as distinguished from LATENT HEAT (*q.v.*), which produces change in state without change of temperature.

Sensitive Flame (*Sound*). *See* FLAME, SENSITIVE.

Sentimentale; Sentimento, Con (*Music*). With feeling.

Senza (*Music*). Without; as SENZA REPETITIONE, without repeats. *See also* SORDINI.

Separately Excited Dynamo (*Elect. Eng.*) A dynamo whose field magnets are excited by current supplied from a separate source, *e.g.* another dynamo. *See also* DYNAMOS.

Separation Cake (*Chem. Eng.*) *See* SEEDING.

Sepiolite (*Min.*) A synonym for MEERSCHAUM (*q.v.*)

Septaria (*Geol.*) *See* CLAY IRONSTONE.

Septet, Septetto (*Music*). A composition for seven voices or instruments.

Septic Tank System (*Sanitation*). A system of treatment of sewage in which the sewage is collected in a covered tank somewhat resembling the old and discarded cesspool. The sewage is introduced below water level, and the outlet is also below the water line. The sewage is passed through the tank very slowly, and is acted on by micro-organisms which break up the solid matter. The advantage of this is that little or no solid matter is deposited. The effluent from the tank is then aërated by flowing over a weir in a thin stream, and is next passed through beds of coke. This system was introduced at Exeter in 1895 by the surveyor of that city, and it is claimed for it that the suspended matter is removed almost completely, and that in the tank itself over one-fourth of the organic carbon in the sewage is removed. In some later forms the submerged inlet is discarded, as it is said to produce more disturbance in the tanks. A separate sludge compartment with a sludge pump may also be provided. *See also* SANITATION.

Sequence (*Music*). The repetition of a musical figure at different pitch. Sequences may be of any length, and are of two kinds, Real and Tonal. A real sequence is one in which every interval of the figure is repeated exactly, and is chiefly made use of for modulation. A tonal sequence is one in which the repetition is confined to the same key; hence the intervals are not exactly repeated. The following shows one example of each kind of sequence.

REAL SEQUENCE.

TONAL SEQUENCE.

See also ROSALIA.

Serdab (*Architect.*) A secret chamber in an ancient Egyptian tomb. *See* MASTABA.

Sereno (*Mus.*) Tranquil.

Serge (*Woollen and Worsted Manufac.*) Serge is composed of crossbred worsted yarns, and is made in medium and heavy cloths for suitings and overcoatings. A union serge is one in which cotton warp and worsted weft is used. *See* WORSTED, *under* WOOL.

Seriatà, Con; Serio, Serioso (*Music*). In a serious, grave manner.

Series (*Elect.*) Conductors are said to be in SERIES when they are so connected that a current passes through them in succession, *i.e.* when the end of one conductor is connected to the beginning of the next.

Series Dynamo and Motor (*Elect. Eng.*) *See* DYNAMO *and* MOTOR.

Serif (*Typog.*) The fine lines and cross strokes on the top and bottom of certain styles of type, *e.g.* M. *Cf.* SANSERIF.

Serpent (*Her.*) The serpent as a charge is represented either erect, involved (in form of a circle), or nowed (tied in a knot).

—— (*Music*). A bass wooden instrument, bent in serpentine form, covered with leather, and having a cupped mouthpiece like a trombone. It is now nearly obsolete, its place being taken by the EUPHONIUM (*q.v.* p. 438). Amongst composers who made use of the serpent may be mentioned Mendelssohn in his *St. Paul*, etc.

Serpentine (*Geol.*) A soft rock capable of being easily carved into ornaments, and usually of a pattern reminding one of that found on some snakes. This colouring is developed chiefly by the prolonged exposure to sea water. Serpentine was in all cases originally an ultrabasic rock of eruptive origin. It consisted chiefly of Olivine and one or more of the Pyroxenes which have been subsequently hydrated by water circulating deep within the earth's crust. Serpentines may be of any age. Some Scottish serpentines are of Tertiary age.

—— (*Min.*) A hydrous silicate of magnesium with traces of alumina and ferrous oxide. It is a rock rather than a mineral. It results from the hydration of several ferromagnesium silicates in decomposition. It is much used as an ornamental stone. The chief British localities are Portsoy in Banffshire, the Lizard, the Shetland Isles, Anglesea, co. Galway, and co. Wicklow.

Serpollet Boiler. *See* BOILERS.

Serve Tube. A boiler tube having ribs radiating from the inner periphery of the tube, about a quarter of the diameter in length. They increase the surface, and hence the heat transmitting power of the tube. Compare the ROW TUBE, the principle of which is only applicable to flexible and ductile metals.

Service (*Plumb., etc.*) (1) The delivery of water or gas to a building. (2) SERVICE PIPES (*q.v.*)

Service Pipes (*Plumb., etc.*) The water or gas pipes inside a building are termed Service Pipes, and often alluded to collectively as the Service.

Service Reservoir (*Civil Eng.*) A reservoir from which water is supplied directly to a town; situated at a sufficient elevation to force the water to the top of the highest building. Their main objects are to provide a reserve of water for sudden emergencies (*e.g.* a fire, a broken main, etc.), and to enable a uniform pressure and a uniform rate of pumping to be maintained.

Service Tree (*Botany*). The true Service Tree is *Pyrus domestica*; the Wild Service Tree is *Pyrus torminalis*.

Serving. Covering the surface of a rope with yarn, etc., to prevent abrasion.

Servitor (*Glass Manufac.*) The glassmaker who fashions and forms the body of articles for the "workman" to finish. The second man in a set or "chair" of workmen. *Cf.* FOOT BLOWER *and* WORKMAN.

Sesame Oil. A medicinal oil expressed from the seeds of *Sesamum indicum* (order, *Pedaliaceæ*). The plant is cultivated in India.

Sesquialtera (*Music*). An organ pipe of several ranks (*see* MIXTURE).

Sestet (*Music*). A composition for six voices or instruments.

Set (*Carp., etc.*) The teeth of a saw are bent sideways; this is called the SET of the saw.

—— (*Typefounding*). The placing of letters or characters on the body or shank in such manner as will secure apparent uniformity of space between them when arranged in every possible form.

—— (*Typog.*) The term indicates the width of body of a type; this determines the amount of blank space on each side of a letter when printed.

—— *or* **Sett** (*Eng.*) (1) A deformation or deflection of an object, due to stresses. (2) A form of chisel with a handle used in cutting bars in the smithy.

—— *or* **Sett** (*Textile Manufac.*) The gauge of the cloth. The term has a different meaning in different centres. A 30s set Glasgow would be 30 × 40 in 37 inches; Bradford, the same number in 36 inches; and Dewsbury and the Heavy Woollen district in 90 inches. The more correct and simpler meaning is the number of reeds in one inch and the number of threads in each reed; *e.g.* 10s reed 4s equals a cloth of a set of 40 threads per inch.

Set *or* **Set Up** (*Typog.*) To place type in order so as to form words, etc., as represented by the copy (*q.v.*) for the purpose of printing; to compose.

Set Off (*Build.*) *See* OFF SET.

—— (*Plumb.*) A bend in a pipe.

—— (*Typog.*) Is caused when pressure is brought to bear on printed work before the ink is properly dry; *i.e.* the ink in its soft condition smears the sheet above or below.

Set Off Blanket (*Print.*) A blanket placed over the cylinders of a perfecting machine to absorb the surplus ink from the printed side of a sheet when being perfected up.

Set Off Paper (*Print.*) Paper to which some preparation has been applied, *e.g.* oil or glycerine; used to prevent the set off (*q.v.*)

Set Out (*Leather Manufac.*) *See* SETTING.

Set Screw (*Eng., etc.*) A screw used for adjusting some part of a piece of mechanism or for holding it in place when adjusted.

Set Square. A drawing instrument consisting of a right angled triangle made of wood, ebonite, etc. The acute angles are usually 60° and 30°, or both of 45°, but other angles are occasionally used.

Sett (*Build.*) A squared block of hard stone used for paving roads where the traffic is heavy. The stone is generally Dolerite, but granite is also used in many cases.

—— (*Textile Manufac.*) *See* SET.

Setter (*Pot.*) A shallow flat seggar in which, bedded upon ground flint, plates, dishes, saucers, and other flat ware are fired in the bisque oven (*q.v.*)

Setter Up (*Lace Manufac.*) A specialist who devotes his whole attention to the adjustment of the inside of a lace machine.

Setting (*Eng., etc.*) (1) Fixing the parts of machinery in their correct positions. (2) Bending the teeth of a saw. *See* SAW SETTING.

—— (*Leather Manufac.*) Leather in the wet state is laid flat on a table, and "set out" by means of a stone or metal slicker. The leather is stretched and set out until no growth marks or creases are visible and until quite flat. Also done by setting out machines.

Setting Block (*Eng.*) A block of iron with a curved edge, on which a saw is laid when the teeth are being set by hammering.

Setting Coat (*Plast.*) The finishing in two or three coat work.

Setting Hammer (*Eng., etc.*) A hammer with a thin pane or point, used for saw setting (*q.v.*)

Setting of Slide Valves (*Eng.*) *See* SLIDE VALVE.

Setting of Tools. *See* SHARPENING OF TOOLS.

Setting Out (*Carp. and Join.*) Marking lines on the prepared stuff (wood) for the cuts, grooves, and the various joints required in the construction of a piece of work. Preparing a working ROD (*q.v.*) from which the sizes of the various parts of the construction are ascertained and worked to.

—— (*Eng.*) Marking the lines, centres, etc., on a rough casting, forging, etc., preparatory to machining and fitting.

—— (*Surveying*). *See* RANGING.

Setting Over (*Eng.*) When conical or tapering work has to be turned in a lathe by means of the slide rest, the back centre or poppet is moved parallel to itself in a direction at right angles to the lathe bed, and fixed in such a position that the slant side of the conical piece of work lies parallel to the central axis of the lathe. This movement is termed Setting Over.

Setting Rule (*Typog.*) *See* COMPOSING RULE.

Setting Stick (*Typog.*) A COMPOSING STICK (*q.v.*)

Setting Stuff (*Build., etc.*) *See* FINE STUFF.

Settlement (*Build.*) (1) The term applied to the squeezing out of the mortar in the horizontal joints of brick and stone walls. (2) The general shrinkage which takes place in a new building.

Set Up (*Met.*) A machine for shortening and thickening a bloom that has been lengthened out by the squeezer.

—— (*Typog.*) *See* SET.

Set Work (*Eng., etc.*) Repetition work, *i.e.* the production of numbers of similar objects.

Seven Pound Lead (*Plumb.*) This expression means that one foot square will weigh 7 lb. The thickness of sheet lead is known by its weight per foot super.

Severies (*Architect.*) The cells or panels between the ribs in Gothic vaulting. *See* CELL *and* RIB AND PANEL VAULT.

Sèvres (*Porcelain*). The National Porcelain Manufactory of France originated at St. Cloud at the close of the seventeenth century. The manufactory proper was established at Vincennes in 1740. About twenty years later it was removed to Sèvres. It has always received Government support. Until the end of the eighteenth century Soft Paste was exclusively made, and it is celebrated as the finest type of soft paste extant. From about the year 1800 Hard Paste was produced, and it has been continued up to the present time. The most celebrated period of Sèvres Porcelain was the middle of the eighteenth century, when magnificent wares were produced, ornamented with rich chased gilding, combined with beautiful flower paintings and also paintings after Watteau and Boucher. The finest colours employed were dark blue (Bleu du Roi), turquoise, rose pink, and apple green.

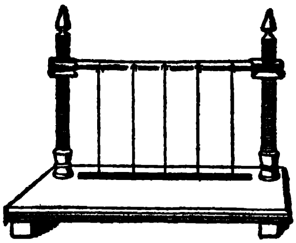
Sewage Removal and Disposal. *See under* SANITATION.

Sewer (*Sanitation*). According to the Public Health Act, 1875, a sewer means the channel receiving the drains of two or more houses or separate premises, and includes sewers and drains of every description, except drains to which the word "drain" as interpreted by the Act applies, and those under the control of any authority having the management of roads and not being a local authority under the Act.

Sewing (*Bind.*) This term comprehends the usual methods of fastening together in proper order the separate sections or sheets which make up a volume, the work being done on a sewing press or by a machine. The principal methods are known as (1) Flexible sewing and (2) Ordinary sewing. In the former method the thread with which the book is sewn is passed completely round each of the bands (*q.v.*) in the process of sewing, the bands being *outside* the sections. In the latter method the thread simply passes over and outside the bands, which are

"sawn in" to facilitate the process. Flexible sewing, therefore, is best adapted for books likely to be subjected to much usage. *See* BOOKBINDING; KETTLE-STITCH; OVERSEWING; SAWING IN; SEWING PRESS; STABBING; *and* STITCHING.

Sewing Press (*Bind.*) An apparatus on which the sections (sheets) forming a volume are placed to be sewn together by hand. The five strings seen in position are the cords or bands (*q.v.*) which are fastened at the top to loops on the crossbar termed lay cords, and are fixed at the other end by means of small implements called keys, which pass through the slot in the bed of the press.



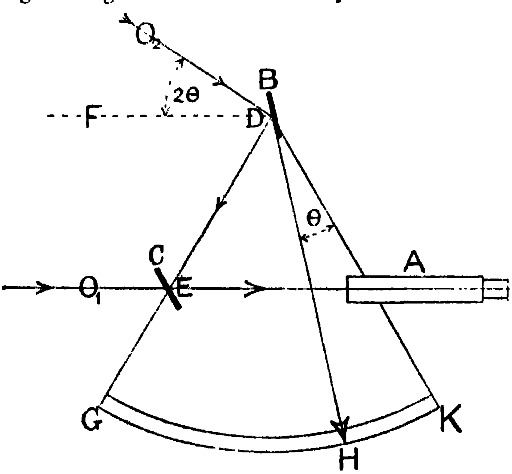
SEWING PRESS.

The sections are placed in one at a time, in numerical order, on the bed of the press with the backs against the cords. The threaded needle, being inserted at the top of the page, is passed along the inside of the fold of the section by the left hand until it is opposite the various bands, when it is thrust through the paper, and the thread is either passed completely round, *i.e.* encircles the band, as in the case of Flexible sewing (*see* SEWING), or simply passes outside the band before re-entry, as in Ordinary sewing.

—— *See* SEWING, KEY, *and* LAY CORD.

Sexpartite or Sixpart Vault (*Architect.*) One of the earliest forms of rib and panel vaults. It was used before the introduction of the pointed arch overcame the difficulty of constructing vaults over spaces which were not square on plan. In a sexpartite vault two bays of the aisle are included in one of the nave. The vault over each rectangle is divided into six compartments by ribs, and all the ribs are arranged as semicircles. *See* RIB AND PANEL VAULT *and* QUADRIPARTITE VAULTING.

Sextant (*Optics, etc.*) An instrument for measuring the angle subtended at the eye of the observer



SEXTANT.

by two distant objects. Let O_1 be a ray from the first object; the telescope A is placed so as to receive this ray directly. O_2 is a ray from the second object, falling on a movable mirror B, by which it is reflected to the mirror C, and thence to the telescope. C is silvered on one-half of its surface only, in order that the ray O_1 may be transmitted through one-half along the path O_1A; while the ray O_2 is reflected by the other half along the path DEA. An arm DH, turning on an axis at D, carries the mirror B. If the ray O_2 be parallel to O_1, the mirror B must be placed parallel to C; H then coincides with the zero of a graduated scale engraved along GHK. If B has to be turned through an angle KDH, in order to reflect the ray O_2 along the path DEA, then the angle O_2DF, which is the angle between the rays O_1 and O_2, is twice the angle HDK. Each degree on the scale GK is numbered as two degrees, and the angle required can then be read off at once. The instrument derives its name from the fact that the arms DK and DG are at an angle of 60° with each other. In an older form these arms were at right angles, and the arc GH was a quarter of a circle; this type was termed a QUADRANT. The instrument is used at sea to measure the angular distance between two celestial bodies, or between one such body and the horizon. Its most important use is to find when the sun reaches its greatest altitude; the instant when this occurs is the time of the sun's Transit (*see* TRANSIT), that is, the time of apparent Solar Noon. This time is reduced to the Mean Noon, and by comparison with the chronometer, which shows the exact mean time at Greenwich, the longitude can be found.

Sextet (*Music*). *See* SESTET.

Sextuplet (*Music*). A group of six notes to be performed in the time of four.

Sforzando, Sforzato (*Music*). Forced, accented. Usually abbreviated to *sf* or *sfz*. Applies to single notes or groups of notes which are to be strongly emphasised. *Cf.* RINFORZANDO.

Sfregazzi (*Paint.*) The Italian term for the method of shading employed by the Venetian school of painters. It consisted of dipping the finger in colour and drawing it once over the part to be shaded, the result being a soft and uniformly thin shadow.

Sgraffito (*Architect.*) A method of treating a small surface, consisting in covering a coloured plaster with a white coat, and then forming the design by scratching away parts of the latter and exposing the ground.

—— (*Dec.*) A method of decoration effected by drawing black figures on a white ground, or *vice versa*, the outlines being accentuated by hatchings. Often carried out in stucco. *Cf.* GRAFFITO.

Shackle (*Eng., etc.*) A loop at the end of a bolt, etc., to which a hook or chain can be fastened.

Shackle Insulator (*Elect. Eng.*) An insulator fixed between the ends of two wires or the two ends of a cut wire.

Shade (*Art*). (1) A gradation of colour. (2) The parts of a picture or drawing represented as unilluminated. (3) A colour to which black has been added. Just as white when added to a colour in different proportions gives a variety of tints, so when black is added the result is a variety of shades. When a colour is viewed in a somewhat dark room, it has the appearance of a shade as compared with the appearance the colour would present if viewed in a strong light. *See* COLOURS, HUE, TINT, *and* CHIAROSCURO.

Shading (*Art*). The method of representing shadows, or obtaining relief, effected by gradations of colour tones or hatching. *See* CHIAROSCURO *and* HATCHING.

—— (*Eng.*, *etc.*) Shading is used in mechanical drawings both to give a natural appearance to views showing the external surface of an object, and also to indicate on a section the material of which the object is composed. Various conventional methods of shading are used for this purpose. *See* SECTION.

Shadow. The region of apparent darkness on a surface, due to the interception of light by an opaque body, the shadow being an outline of the illuminated portion of the intercepting body.

—— (*Phys.*) An area or space within which illumination from some particular source or sources is cut off by an opaque object. The term is further extended in physics to the cutting off of other forms of radiation and radiant energy. Thus the cutting off of heat rays produces a shadow whose boundaries may be detected by the use of the thermopile. A sound shadow may be detected in some cases by the ear, in other cases by the use of the sensitive flame, etc.

Shadow Bands (*Astron.*) The curious appearance of dark and light bands which are observed to travel on the surface of objects during the commencement and end of the total phase of an eclipse of the sun.

Shadow Photometer (*Light*). *See* PHOTOMETERS.

Shaft (*Architect.*) The central division of a column between the base and capital. *See* COLUMN *and* ARCHITECTURE, ORDERS OF.

—— (*Eng.*) A rod or bar, usually cylindrical, which is used to transmit rotation.

—— (*Mining*, *Civil Eng.*, *etc.*) A vertical (less frequently inclined or sloping) hole leading into a mine, tunnel, or other underground working. The sides are lined with timber, masonry, or iron, to prevent collapse. The shaft may be intended solely for ventilation, or may contain ladders, winding gear, pumping appliances, etc. *See* MINING.

—— (*Silk Manufac.*) *See* HEDDLE.

Shafting (*Eng.*) A comprehensive term for a number of shafts; often used to include their bearings, pulleys, etc.

——, **Flexible** (*Eng.*, *etc.*) Shafting made of some flexible material, or constructed with joints which permit lateral bending while rotary motion is being transmitted, are used to actuate certain kinds of mechanism, *e.g.* small drills such as those used by dentists. A flexible shaft is also used in certain cases where a very high velocity of rotation occurs, as in some forms of steam turbine, in order to diminish the risk of fracture.

Shaft Tunnel (*Eng.*) The passage or tunnel through which the shaft of a screw propeller runs from the engine to the stern of the vessel.

Shake (*Carp.*, *etc.*) Cracks or fractures produced in timber, due to shrinkage. *See* WOODS.

—— (*Mining*). A crack or opening in a vein or rock.

—— (*Print.*) An imperfect impression caused by a defect in the press or machine, and giving a blurred appearance to the printing.

—— *or* **Trill** (*Music*). *See* ORNAMENTS, p. 478.

Shale (*Geol.*) Sedimentary rocks originally deposited as thin layers of mud or silt, with pauses between the deposition of each layer, so that slight differences of mineral character occur at small vertical intervals, and the rock, in consequence, splits easily in directions parallel to them. In Scotland Shales are called Blaes. In the North of England they are called Plate, and, if silicious, Shiver. Shale in Scotland usually means Oil Shale (*q.v.*) *Cf.* SCHIST.

Shallow Water Deposits (*Geol.*) Sedimentary rocks deposited in water of small depth, which commonly alternate with other sediments that have been formed at the surface. The prevailing types are shingle and gravel, coarse and fine sands, silts and loams, with, more rarely, clays. Limestones seldom occur; but shell marl, and also diatom earth, may form part of shallow water deposits of freshwater origin. Impressions of raindrops and casts of desiccation cracks formed by the drying of clay beds, etc., are specially characteristic of shallow water deposits. Ripple marks also are of common occurrence.

Shallow Wells (*Economic Geol.*) This term should be understood to mean wells where water supplies are chiefly drawn from waters percolating into them directly from the surface, as distinguished from those wells whose supply is exclusively derived from waters which have circulated through the solid rock. A well supplied from the water which generally occurs at the bottom of the river gravels of the Thames Valley is a good example of the former; while a well sunk deep into the chalk of the same district, and exclusively supplied from that source, is a typical example of the latter. Shallow wells are particularly liable to surface contamination from middens, cesspools, drains, and other sources of pollution, and are often, therefore, dangerous sources of disease. In those wells in which proper care is taken to exclude all surface waters, no such danger can exist, even though their actual depth may be but small. On the other hand, a well of considerable depth, if surface waters are not rigidly excluded, may at any time prove to be a source of danger. *See also* SANITATION.

Shamrock (*Botany*). *Trifolium repens* (order, *Leguminosæ*), a plant common in most temperate regions. The original shamrock is believed by some writers to have been *Oxalis acetosella*.

Shank. (1) A handle. (2) In the foundry a bent bar serving as a support for a ladle. (3) The main part or body of a tool such as a drill, slide rest, tool, etc. *Cf.* TANG.

—— (*Join.*) The straight part on the end of a wreathed handrail.

—— *See* TYPES.

Shap Granite. *See* BUILDING STONES.

Shaping (*Eng.*) Work carried out in the SHAPING MACHINE (*q.v.*)

Shaping Machine (*Eng.*) A machine tool in which a tool resembling that used in a slide rest is moved backward and forward in a horizontal line, so as to act on a piece of work fixed upon the table of the machine. Its cutting action is similar to that of a planing machine, but it is more convenient for use in the case of small or awkwardly shaped objects.

Sharp (*Music*). Marked by ♯. It raises the note before which it is placed a semitone. *See also* DOUBLE SHARP.

Sharpened 5th (*Music*). The chord consisting of the Dominant, Leading-note, Sub-dominant, and sharpened Supertonic, so called by Theorists opposed to the Day theory (*q.v.*)

Sharpening of Tools. This includes (1) GRINDING on a grindstone or emery wheel, or an equivalent operation, in order to bring the edge approximately to the required form (2) SETTING or sharpening proper, in which the final form is given to the cutting edge by oil stones or hones. The final setting is as important in the proper sharpening of tools for cutting metal as in the much keener edges used in woodwork, if a good finish or accurate work is required.

Sharpening Slip (*Carp., Eng., etc.*) A piece of stone for sharpening or setting the edges of curved cutting tools.

Sharpe's Classification (*Architect.*) *See* CURVILINEAR.

Sharp Mixture, Shrill Mixture (*Music*). One of the stops in organs. *See* p. 439.

Shave Hook (*Plumb.*) A scraper for shaving off the lead where a joint has to be made.

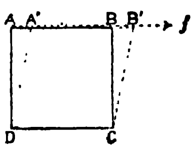
Shaving (*Leather Manufac.*) Hides and skins for certain purposes are shaved to even substance. This is one of the most delicate operations in finishing leather. The operation is mostly done by hand on an upright beam with a knife, the edge of which has been turned at right angles. For rough work machines are now used.

—— (*Plumb.*) Paring away the surfaces from two pieces of lead that are to be soldered together.

Shaving Tub (*Bind.*) The receptacle into which the paper falls when the edges of a book are being cut previous to binding.

Shawm *or* **Shalm** (*Archæol.*) That mentioned in the Prayer Book is, according to the late Sir John Stainer, the ramshorn or horn trumpet.

Shear (*Phys., Eng., etc.*) Let A B C D be any piece of material, with the edge D C rigidly fixed. Let a tangential force, whose amount is f units of force per unit area, be applied to the face A B in the direction of the arrow. Then the material will in general be distorted into the form A′ B′ C D. The angle A D A′ or B C B′ is termed the SHEAR *or* SHEARING STRAIN, and the force f the SHEARING STRESS.



SHEAR.

A shear can be produced without alteration in the volume of a body, as, for example, when one end of a cylindrical rod or wire is rigidly fixed, and the other end twisted. This is the form of stress which exists in shafts which are used to transmit any rotary motion. The ratio

$$\frac{\text{Shearing Stress}}{\text{Shearing Strain}}$$

is termed the COEFFICIENT OF RIGIDITY, COEFFICIENT OF TRANSVERSE ELASTICITY, MODULUS OF RIGIDITY, or simply the RIGIDITY.

Shearing (*Eng.*) (1) Cutting material by means of shears or a shearing machine. (2) The production of a Shearing Stress or Strain. *See* SHEAR.

—— (*Geol.*) A term applied to the mechanical results upon rocks resulting from a differential movement of the part on one platform as compared with that immediately below. The phenomenon is one that usually accompanies great terrestrial disturbances deep within the earth's crust.

Shearing Machine (*Eng.*) A machine driven by power and provided with strong jaws or knives for cutting iron plates or bars. Largely used in boiler shops, etc.

Shearing Strain (*Eng.*) *See* SHEAR.

Shearing Stress (*Eng.*) *See* SHEAR.

Shear Legs (*Eng.*) *See* SHEERS.

Shears. Cutting tools for sheet metal, glass, etc., having a mode of action resembling that of scissors; the tool may be actuated by hand or power; in the latter case it is usually termed a SHEARING MACHINE *q.v.*)

Shear Steel (*Met.*) Steel which has been formed from a number of bars of common steel made into a FAGOT (*q.v.*) This is heated to the welding temperature and drawn out. If the operation is repeated DOUBLE SHEAR STEEL is produced.

Sheave (*Eng., etc.*) (1) A small wheel with a groove in its periphery in which a rope or belt can run. (2) The central portion or disc of an ECCENTRIC (*q.v.*)

Shed (*Textile Manufac.*) The space or opening between warp threads when they are separated for the shuttle to pass through. *See* OPEN SHED, CLOSED SHED, *and* LOOM.

Shedding (*Textile Manufac.*) The primary movement of the loom. The formation of a division or "shed" in the warp threads by the healds to allow the shuttle to pass through, so as to effect an interlacing of warp with weft. The shedding motions are: TAPPET, DOBBY, JACQUARD (*q.v.*) *See also* LOOM.

Sheep (*Bind.*) The term applied to various cheap kinds of binding done with sheepskin.

Sheepsfoot (*Print.*) A hammer with an iron handle which has a claw at the end. The hammer is used for fastening formes in the press, and the claw for raising the formes

Sheer Poles (*Eng.*) The poles of a set of SHEER LEGS: SHEERS.

Sheers. A tall hoisting apparatus consisting of two or three pieces of timber, etc., erected so as to incline towards each other at the top, where they are fastened together and the necessary tackle for hoisting attached. Sheers are employed for masting and dismasting ships, putting in marine boilers and engines and other similar operations.

Sheet (*Print.*) The perfected section of a printed work, *i.e.* printed from outer and inner formes.

Sheet Glass. This is used chiefly for glazing, and has entirely superseded Crown glass for the purpose, owing to reduction of waste and the larger size of the sheets. Figured rolled sheets of various colours and patterns are manufactured in a manner similar to rolling plate glass, the pattern being incised upon the roller. These sheets are cut up into shapes suitable for designs in leaded lights. *See* FURNACE, GLASS MANUFACTURE, *and* CROWN GLASS.

Sheet Iron (*Eng., etc.*) Thin plates of iron, such as are used for making TIN PLATES (*q.v.*) The thicker plates (those above ¼ in.) are not termed sheet iron, but BOILER PLATES, etc.

Sheet Lightning (*Meteorol.*) A sudden glow which is not confined to a line, as in the case of

ordinary lightning. It is probably the reflection of a more distant flash of ordinary lightning occurring in many cases below the horizon.

Sheet Metal Gauge (*Eng.*) A flat plate with notches, whose width serves to determine the gauge or thickness of sheet metal. The width of the notches may correspond to the numbers of the various WIRE GAUGES (*q.v.*) or may be definite fractions of the inch, etc.

Sheet Piling (*Civil Eng.*) Piles driven into the ground close together, so as to form a continuous row. They are usually braced together, and the joints filled up by caulking, in order to form a water-tight partition. In large works two parallel rows of sheet piling are used, and the space between them is filled up with clay.

Sheet Tin (*Met.*) This term is applied to thin plates of good wrought iron or mild steel, coated with metallic tin. *See* TIN PLATES.

Shell (*Eng.*) The outer part of various objects, *e.g.* of a boiler, considered apart from its fittings, or of a ship, apart from the internal work, machinery, etc.

Shellac. A brittle resinous substance produced by an insect. It consists of about 85 per cent. resin, 5 per cent. wax, colouring matter, etc. There are six varieties in commerce, viz. stick lac, lac dye, shell lac, seed lac, button lac, and shellac rods. It is largely used in the manufacture of wood polishes and of spirit and other varnishes. *See* LAC *and* RESINS.

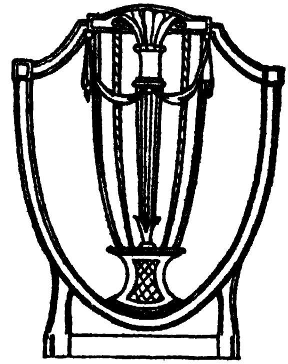
Shell, Magnetic. *See* MAGNETIC SHELL.

Shell Marl (*Geol.*) Usually a freshwater deposit formed at the bottom of quiet sheets of water, and consisting partly of the dead shells of freshwater mollusca, but mainly of a mixture of fine clay and calcareous matter resulting from chemical precipitation. The word "marl" properly means any rock that readily crumbles away on exposure to the weather. *See* MARL.

Shell Plates (*Eng.*) The plates composing the outer part or shell of a boiler.

Shell Transformer (*Elect. Eng.*) *See* TRANSFORMERS.

Sheraton. In this country Sheraton furniture stands next in repute to Chippendale. Though not so original as his predecessor, Thomas Sheraton showed more skill in the adaptation of French forms, *viz.* Louis Seize and Empire; hence his work covers a wider field. Sheraton was born at Stockton-on-Tees in 1751, came to London in 1790, and the following year published *The Cabinetmaker and Upholsterer's Drawing Book*, which was succeeded by an accompaniment and an appendix. The second edition of this standard work appeared in 1793, and the final one in 1802. In 1803 was issued *The Cabinet Dictionary; or, Explanation of All Terms used in the Cabinet, Chair, and Upholstery Branches*, and next year he commenced the publication in serial form of *The Cabinetmaker and Artist's Encyclopædia*, to be completed in 125 parts, of which but thirty were before the public at the time of his demise in 1806. Sheraton was trained for the profession of an architect, and his studies proved of great value in his life work. His designs are drawn to scale with mathematical precision, and he effected a meritorious combination of such diverse styles as those of Louis XVI., Sir W. Chambers, and the brothers Adam; he also rendered in wood the famous Queen Anne swan-necked pediments. Sheraton's designs comprise painted wood mantelpieces, drawing-room panels, pier tables, square mirrors, door cases, cornices in the aforenamed blends, satinwood cabinets, clock cases, commodes, toilet tables, Pembroke tables and chairs. The satinwood pieces were painted in devices of wreaths, floral and ribband festoons, cornucopiæ, medallions, trophies, and allegorical figures. There is a beautiful toilet table (No. 635) at South Kensington in the latter style. For his veneers Sheraton used the most costly mahogany; for inlays, purple wood, box, and occasionally stained woods. To divide his panels he employed the Ionic pilaster. Among the novelties which we owe to Sheraton may be named the kidney shaped writing table; the sideboard with concave fronts, for which the serpentine form was occasionally substituted; and last, not least, "Rudd's Table," for toilet purposes, fitted with a central and two flanking mirrors, which last, rising by a quadrant, could be turned from a vertical to a horizontal position, thus reflecting the back of the head. A reversion in the type of chairs favoured by him was that to the ancient classic curule, the seats ornamented with masks of men and animals. The metal employed for the Empire work was brass; unfortunately this led him to decorate his carved wood pieces with bronze green or gilt. The effect after lapse of time proves this to be a serious error, as may be seen in Nos. 45 and 46 at South Kensington. The only other specimens of Sheraton at this Museum are Nos. 407 and 408, a pair of marqueterie chairs. Among the curiosities devised by Sheraton may be mentioned "gouty stools," chamber horses, "library steps planned to fold up within the Royal writing table," *bidet* dressing tables transformed by closing into stands, and "a pulpit with inlaid panels and a sounding board surmounted by an acorn shaped ornament." Sheraton's *magnum opus*, *The Cabinetmaker and Upholsterer's Drawing Book*, was republished in 1895 by Messrs. Batsford.



CHAIR BACK (SHERATON).

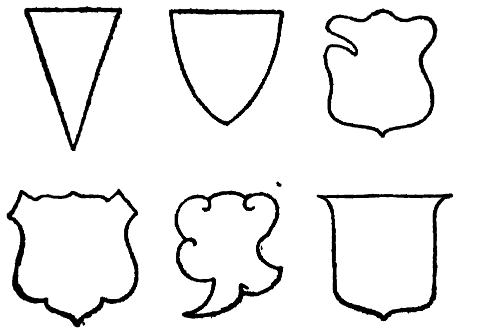
Sheringham Valve. This ventilator consists of a small vertical trap door (usually 9 in. by 3 in.) in the wall near the ceiling, hinged at the bottom and cased at the sides, so that the air, which enters through a perforated brick or grating, is directed upwards. It can be opened or closed by means of a balanced weight.

Shield (*Arm.*) A piece of defensive armour made of wood, hide, or metal, or a combination of these substances. It was carried on the left arm, and used for warding off blows or missiles. The earliest known examples are circular in shape and almost flat on the outside; they date from the Bronze age. The shield continued in use until the sixteenth century, by which time firearms had rendered it practically useless. The Norman shield was triangular or kite shaped, eventually becoming shorter and convex on the outside, *i.e.* curving towards the body, the latter form being known as a "heater" shield. *Cf.* SCUTUM.

Shield (*Civil Eng.*) A structure used in the excavation of tunnels, especially through loose or wet strata. The outline commonly follows the shape of the tunnel; it supports the roof and protects the men who work inside the shield. As the material in front is removed, the shield is pressed forward by rams or other mechanism, and the masonry of the tunnel is filled in behind it. In some cases the shield itself carries mechanical excavating appliances, driven by power.

—— (*Eng.*) In general a cover or screen employed to protect some part of a machine or to guard workmen from injury by the mechanism.

—— (*Her.*) The escutcheon upon which heraldic charges are blazoned. The space enclosed by its bounding lines is termed the *Field*, the colours used in the field are termed *Tinctures*, the lines used in dividing the field are termed *Partition Lines*, and the various objects which appear on the field are known as *Charges*. The heraldic shield or escutcheon has assumed various forms at different periods. The



5 6

1. Triangular Shield.
2. Heater shaped Shield.
3. Shield *à bouche*.
4. Shield of Georgian period.
5. Rococo Shield.
6. Modern Shield.

most ancient are simple, but in later times their outlines became more elaborate. The custom of blazoning arms on shields arose in the Middle Ages, when nobles and knights in armour bore devices on their shields in battle for the purpose of distinction. *See* HERALDRY *and* POINTS OF SHIELD.

——, **Electric and Magnetic.** *See* SCREEN, ELECTRIC AND MAGNETIC.

Shielding, Electric and Magnetic. The action of an electric or a magnetic screen. *See* SCREEN.

Shield of Pretence (*Her.*) A small shield bearing an escutcheon is in some cases placed upon the centre of another shield. The shield of an heiress is sometimes thus "pretended" upon the arms of her husband. The arms of Hanover were placed on a shield of pretence on the Royal Arms of England during the reigns of the kings of that house.

Shifting Link (*Eng.*) The slotted link to which the ends of the eccentric rods are attached. *See* LINK MOTION.

Shingle (*Geol.*) A term that ought properly to be restricted to the accumulation of rounded stones worn by the prolonged action of water in motion, which would leave the term gravel for the angular and subangular stones such as floor so much of the Thames Valley and the Basin of the English Channel.

Shingler (*Met.*) A workman employed in SHINGLING (*q.v.*)

Shingles (*Build.*) Boards of V-shaped section, commonly ½ to 1 in. thick at one edge, but tapering towards the other edge. They are made from some wood which splits easily along the grain, such as some species of oak. Used for roofing, fencing, etc.

Shingling (*Met.*) The squeezing and hammering of the ball of spongy iron from the puddling furnace to weld the iron into a bloom or stamp and expel slag, etc.

Ship Canal (*Civil Eng.*) A canal intended for the passage of ships; chiefly differs from an ordinary canal in its greater size, and in the fact that it must be constructed at a low level without embankments. The Suez Canal was originally 26 ft. deep, but this has been increased; most modern ship canals are about 30 ft.

Shippers (*Build.*) A term now frequently used for sound, hard burnt bricks, but of a bad shape.

Shipping. (1) Placing on board ship. (2) A general term for putting in place some movable object, *e.g.* placing a belt on the pulleys.

Shipping Measurements. The extreme length, breadth, and depth of an object measured to the extremities of all projections; they may be taken as approximately equal to the size of the box which would contain the entire object. Shipping charges are based on this size, and not on the actual bulk or weight of the goods.

Ship Plates (*Eng.*) Iron or mild steel plate not of the best quality, but of sufficient tensile strength for use in the hulls of ships.

S.H.M. SIMPLE HARMONIC MOTION (*q.v.*)

Shock (*Eng.*) A sudden stress, whether produced by a blow or otherwise.

——, **Electric.** The effect produced on a living organism by the passage of electricity through the tissues.

Shoddy. Coarse and inferior cloth, composed of the fibre of old woollen or worsted fabrics which have been torn up or "devilled" and respun with the admixture of fresh wool of inferior quality.

Shoe (*Build.*) The lower end of a rain water pipe shooting out from the wall.

—— (*Eng.*) A metal cap placed on the end of beams and poles to prevent undue wear or to facilitate the attachment of other objects, etc.

—— (*Glass Manufac.*) A fireclay box placed on one side of the pot and projecting into the furnace. Used for heating the gathering irons and ponty.

Shone System (*Sanitation*). This system of sewage removal is useful where the ground is flat and there is difficulty in getting a fall. The sewage is collected in cylindrical reservoirs, known as "ejectors," and forced from these tanks through pipes to the outfall by means of compressed air.

S-Hooks (*Foundry*). Iron hooks hanging inside moulding boxes and serving to support the sand.

Shoot (*Silk Manufac.*) *See* WEFT.

Shooter (*Typog.*) *See* SHOOTING STICK.

Shooting (*Joinery, etc.*) Truing the faces or edges of boards, etc., by means of the trying plane.

Shooting Board (*Joinery, etc.*) A board on which a piece of wood is laid when an edge, etc., is being accurately planed. The wood is placed on the shooting board with the edge required to be trued up

projecting over a rabbet or depression, along which the plane is moved. The edge of this depression guides the plane in a straight line.

Shooting Stars (*Astron.*) *See* METEORS.

Shooting Stick (*Typog.*) An implement made of wood, steel, or other hard material, and used in conjunction with the mallet for locking up formes of type.

Shop Front (*Carp. and Join.*) The whole of the front of a shop, etc., woodwork, from the cornice to the pavement.

Shop Tools (*Eng.*) The smaller articles provided by the owners of the workshops, as distinguished from the machine tools on the one hand and the tools which are the private property of the workmen on the other.

Shop Traveller (*Eng.*) A travelling crane used for lifting heavy objects in the workshop. Usually fitted in every department of the engineering shop except that of the pattern makers.

Shore (*Geol.*) The zone between tide marks, which is that of the greatest biological activity, as well as that along which marine erosion chiefly operates.

——, **Shoring** (*Carp.*) Shoring is a method of furnishing temporary support to walls or other parts of a structure during alterations or excavations which affect their stability, or when they show signs of yielding from other causes. For this purpose timbers termed SHORES are used. An inclined support, reaching from the ground to some point in the wall, etc., is termed a RAKING SHORE. Two or more raking shores extending from the same point (or nearly so) on the ground to different points on the wall, form DOUBLE RAKING SHORES, TREBLE RAKING SHORES, etc. An inclined support extending from a point on a shore to some point on the wall above is termed a RIDER. The lower end of a raking shore rests on a flat timber termed a SOLE PIECE or FOOT BLOCK; the upper end rests against a flat timber placed vertically against the wall, and termed a WALL PIECE. Into this wall piece is mortised a rectangular piece of wood termed a NEEDLE; one end of this passes through the wall piece into the wall itself, the other projects sufficiently to enable the top of the shore to abut against it. A FLYING SHORE is a horizontal support extending between two walls, the ends abutting on wall pieces. DEAD SHORES are vertical timbers supporting the masonry over an opening (*e.g.* a shop front). The feet of these shores rest on SLEEPERS or FENDERS, horizontal timbers laid on the ground, and their tops carry transverse members (termed NEEDLES) on which the masonry rests. The adjustment of shoring is largely effected by wedges, and the joints are secured by iron dogs, hoop iron, or additional wooden members nailed or spiked to the main timbers.

Short (*Elect.*) A contraction for SHORT CIRCUIT (*q.v.*)

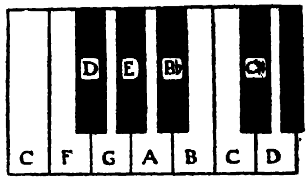
—— (*Met.*) Brittleness in metals, especially iron and steel, due to the presence of certain impurities. *See* COLD SHORT *and* RED SHORT.

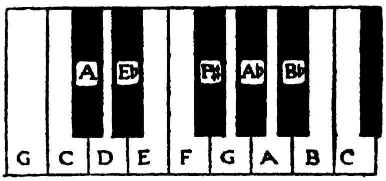
Short Circuit (*Elect.*) An electrical connection between two points in a circuit which provides an alternative path for the current, and thereby diverts it from the main circuit to a greater or less extent.

Short Column (*Eng.*) A column whose diameter is a large fraction ($\frac{1}{8}$ to $\frac{1}{4}$) of its length, and whose tendency to bend under its load may therefore be neglected.

Short Cross (*Typog.*) The shorter and usually the broader bar which divides the inner space of an ordinary book chase.

Short Octave (*Music*). A term given to organs which had an incomplete scale at the lowest end of the manuals. The notes were arranged to give as many "tonics" as possible without the expense of adding the larger pipes of the complete chromatic scale. The order of the sounds differed, but the following shows two arrangements of the notes:





Short Period Comets (*Astron.*) Comets which have periods from three to eight years in length. Spoken of sometimes as Jupiter's family of comets.

Shorts (*Typog.*) A term applied (*a*) when the printed sheets are less than the number required; (*b*) to describe the accented vowels ă ĕ ĭ ŏ ŭ.

Shot Edges (*Carp. and Join.*) The edges of a board which have been planed straight by the process of SHOOTING (*q.v.*)

Shoulder (*Eng., Carp., etc.*) The part of an object at which there is a sudden increase in width or diameter. The term is often restricted to the surface at this point, which is at right angles to the main axis of the object, *e.g.* the portion of a tenon joint which forms the abutment.

Shouldered Arch (*Architect.*) A lintel over a door opening resting on two projecting corbels; a common method of construction in Early English work.

Shoulder Notes (*Typog.*) Notes placed in the margin at the top of a page. *See* NOTES.

Shoulder of Type. *See* TYPES.

Shoulder Plane (*Join.*) A metal rabbet plane for shooting the shoulders of tenons, etc.

Shove *or* **Shive** (*Linen Manufac.*) When the flax is being scutched in order to separate the fibre from the bone or woody stem, the latter is broken up and driven out by revolving blades, and a large quantity of refuse is thus produced which is called "shove" or "shive." It is often, after the tow or short fibres are extracted from it, burned in the scutch mill fires.

Showers, Meteoric (*Astron.*) *See* METEORS.

Shrine. A casket or other receptacle for sacred relics, or a small chapel, etc., sanctified by the presence of such relics. An altar.

Shrinkage (*Foundry*). The contraction of a casting while cooling.

Shrinking Head (*Foundry*). A FEEDER (*q.v.*)

Shrinking On (*Eng.*, *etc.*) Fixing on a tyre, etc., which is made slightly smaller than the wheel to which it belongs. By heating the tyre it expands sufficiently to allow it to be placed in position, and its contraction on cooling holds it firmly in place.

Shroud (*Eng.*) A flange connecting the ends of the separate teeth of a gear wheel. A FULL SHROUD is one whose depth is equal to that of the teeth, so that the latter do not project at all. The wheel gearing with the fully shrouded one will therefore have no shroud. A HALF SHROUD, or flange of half the depth of the teeth, may be employed in the case of both wheels. A shroud increases the strength of the teeth to a very considerable extent, but is difficult and expensive to cast, and the teeth cannot be cut or finished by the aid of rotary cutters. The term "shroud" is also applied to the flanges which support the floats of a waterwheel.

Shrouded Wheels (*Eng.*) Toothed wheels provided with a SHROUD (*q.v.*)

Shunt (*Elect.*) A branch conductor or circuit connected in parallel (*q.v.*) with another or main circuit between two given points. The current divides itself between the two branches in proportion to their conductivity. A shunt may be used for various purposes, *e.g.* to draw off a portion of the main current for some specific purpose, as in the Shunt Dynamo (*q.v.*), or merely to reduce the current in a part of the main circuit, as in the case of a galvanometer. In this instance a shunt is used when the current is too large to be passed through the instrument with safety, or too large to give a readable deflection. If G be the galvanometer resistance, S that of the shunt, the fraction of the current which passes through the galvanometer is $\frac{S}{S+G}$. It is usual, where the amount of the current has to be found, to make S $\frac{1}{9}$, $\frac{1}{99}$, or $\frac{1}{999}$ of G, when ·1, ·01, or ·001 of the main current passes through the instrument. The factor by which the current through the galvanometer must be multiplied in order to obtain the total current is often termed the MULTIPLYING POWER OF THE SHUNT.

Shunt Dynamo (*Elect. Eng.*) *See* DYNAMO.

Shunting (*Elect. Eng.*) Providing or using a SHUNT (*q.v.*)

—— (*Railways*). Diverting rolling stock from one set of rails to another.

Shunt, Multiplying Power of (*Elect.*) *See* SHUNT.

Shunt Wound Dynamo (*Elect. Eng.*) *See* DYNAMO.

Shutter Weir (*Civil Eng.*) A weir consisting of panels or shutters turning about a horizontal hinge, usually placed a little above the centre. When the weir is closed, the top of the shutter is inclined down stream, and the bottom rests against a sill or ledge in the bed of the stream.

Shutting (*Eng.*) Closing up a joint by welding or hammering.

Shuttle (*Weaving*). An oblong shaped hollow receptacle with pointed ends, used in the loom for carrying the weft backwards and forwards through the shed (*q.v.*), so that it may interlace with the warp threads and form woven cloth. The principal woods of which it is constructed are boxwood, cornel, persimmon, and apple-tree. In the hollow part of the shuttle is fixed a tongue or peg, on to which the cop, pirn, or quill, containing the weft is slid. The reciprocating movement of the shuttle is effected by the "picking motion" (*q.v.*) The weft thread from the cop, pirn, or quill is passed through eyes in the shuttle, in order to regulate the tension. *See also* LOOM, SHUTTLING, *and* SLEY.

Shuttle Box (*Weaving*). An enclosure or terminus at each end of the shuttle race, from the one to the other of which the shuttle is ejected and received, and in which the picker or driver works for propelling the shuttle. A bulging steel spring fitted at the side of the box serves to neutralise the force of the shuttle when entering. *See* SHUTTLE.

Shuttle Guard (*Weaving*). A thin wrought iron rod the width of the sley top, and to which it is affixed in order to reduce the chances of a shuttle flying out of shed.

Shuttle Machine, Schiffle (*Lace Manufac.*) That form of Swiss embroidery machine wherein a series of needles and shuttles are employed, constituting it a very speedy machine.

Shuttle Protector (*Weaving*). An attachment to a loom for preventing traps, in case the shuttle fails to reach the shuttle box. Two kinds: (1) Loose reed; (2) Fast reed.

Shuttle Race *or* **Trashboard** (*Weaving*). A long narrow board fixed on the upper part of the sley, and on which the warp threads of the lower part of the shed rest. The shuttle traverses the shuttle race when passing through the shed. The shuttle race should be made of short grained hard wood, well seasoned, so that it will neither split nor warp, and it must have a smooth surface. *See* LOOM.

Shuttling (*Weaving*). The method of controlling the shuttles or bringing the requisite shuttle and kind of yarn into position for the successive sheds in weaving. *See* LOOM.

Si (*Chem.*) The symbol for Silicon (*q.v.*)

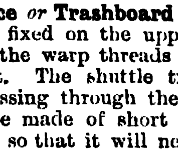
——.(*Music*). The Sol Fa name for B.

Siccative (*Dec.*) *See* DRIERS *and* PATENT DRIERS.

Sicilian (*Textile Manufac.*) A fabric which is similar, as regards materials, to mohair lustre, but thicker weft used, in order to produce a matted appearance.

Sickening (*Mining*). Flouring (*q.v.*)

Side Chains (*Chem.*) When an aliphatic residue enters in any position as a substituent in a ring compound it is called a side chain. Example: Ethyl benzene



here the group CH_2CH_3 is called the side chain.

Side Chisel (*Woodwork*). A chisel with the cutting edge at an angle other than a right angle with the blade. Used in wood turning.

Side Drum (*Music*). *See* MUSICAL INSTRUMENTS, p. 444.

Side Elevation. An external view or drawing of the side of an object.

Side Lever Engine (*Eng.*) An obsolete form of beam engine (*see* STEAM ENGINE), with the beam placed low down, near the base plate. It was one of the earliest forms of marine engine.

Sidenotes (*Typog.*) Notes placed in the margin of a page as distinguished from footnotes. *See* NOTES.

Side Rabbets (*Carp. and Join.*) Planes for planing the right and left hand sides of grooves.

Sidereal Day (*Astron.*) The interval of time between two successive passages of a fixed star over a given meridian.

Sidereal Month (*Astron.*) The time it takes the moon to make her revolution from a given star to the same star again, as seen from the earth's centre.

Sidereal Noon (*Astron.*) *See* SIDEREAL TIME.

Sidereal Time (*Astron.*) The sidereal hour is $\frac{1}{24}$th part of the sidereal day (*q.v.*) The time is reckoned from sidereal noon, *i.e.* the instant when the vernal equinox is on the meridian. It is the hour angle of the vernal equinox or the right ascension of the observer's meridian.

Siderite (*Geol. and Min.*) (1) A synonym for CHALYBITE (*q.v.*) (2) A term sometimes applied to the nodules of clay ironstone commonly met with in connection with the shales of the Carboniferous Rocks.

Siderography (*Engrav.*) Literally, the art of engraving on steel or iron, but more especially a method of engraving effected on soft steel plates, which are subsequently hardened and the design transferred to a soft steel roller, which is in turn hardened and used for printing from.

Siderostat (*Astron.*) A form of instrument composed mainly of a plane reflector and a driving clock, for reflecting the light of any celestial object horizontally in a southern direction. Generally used in conjunction with a telescope mounted horizontally.

Sidestick (*Typog.*) A narrow piece of furniture, straight on one side and tapering on the other. It is placed at the side and at the foot of pages, so that a space is left between it and the chase in which the quoins may be driven with the mallet and shooting stick when locking up.

Side Tank (*Eng.*) A water tank placed along the side of the boiler of a locomotive; used chiefly in small engines such as contractors' locomotives.

Side Tool (*Eng., etc.*) A tool whose end is bent round or so formed that the cutting edge is parallel to the axis of the tool.

Siege (*Glass Manufac.*) The floor or bed of the furnace.

Siemens-Martin Process (*Met.*) *See* IRON *and* SIEMENS PROCESS.

Siemens Process (*Met.*) The production of steel from pig iron by means of an open hearth process in a reverberatory furnace. The pig is mixed with a suitable proportion of scrap steel or malleable iron, melted in the furnace, and spiegel or ferromanganese (*q.v.*) afterwards added. In a modification of this process the pig is fused with iron ores rich in oxide of iron; while in the latest form, termed the SIEMENS-MARTIN PROCESS, both iron ore and scrap iron are used. The furnace is of the regenerative type (*q.v.*), the charge being melted by the combustion of the gases in the chamber of the furnace; by proper regulation of the supply of air, the gases may be caused to exert a reducing or an oxidising effect on the metal, or may be rendered neutral, so as to have no direct chemical effect whatever. Impurities of the pig iron such as phosphorus may be removed in the form of slag by providing a furnace lining of dolomite (*q.v.*), and thus steel may be obtained ready for casting. *See also* METALLURGY.

Sieve. A screen of mesh work composed of various materials and various degrees of fineness (*i.e.* size of opening) according to the particular purpose for which it is required. In assaying, crushed ores, etc., are caused to pass through a sieve of eighty or more meshes to the linear inch.

Sight Feed Lubricator (*Eng.*) A lubricator in which the supply of oil is visible to the eye.

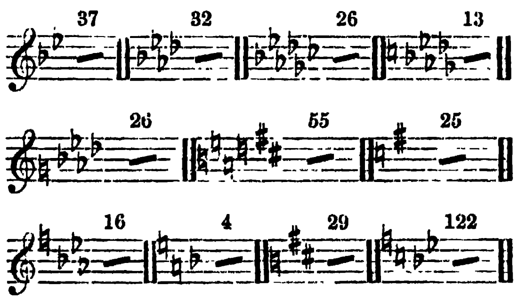
Sight Holes (*Met., etc.*) Openings through which the interior of a furnace can be seen.

Sigillaria. The name given to certain forms of plants found in coal formation; so named from the seal-like markings in their stems. They have no representatives in modern vegetation. Their roots are known as *Stigmaria.*

Signal, Holmes'. *See* HOLMES' SIGNAL.

Signals and Signalling (*Railways*). *See* RAILWAYS.

Signature (*Music*). The signs at the beginning of a musical composition. Signatures are of two kinds, the key and the time. (*See* KEY SIGNATURE *and* TIME SIGNATURE.) When a change of key signature occurs in a composition it is usual to cancel so much of the former signature as is not required. In Beethoven's Sonata in B♭, Op. 106, the following key signatures occur in the fugue for three parts:



—— (*Typog.*) A letter or figure placed in the white line at the foot of the first page of each sheet (or half sheet) of a book, etc., to serve as a guide when the sheets are being folded, and to indicate their order. It also serves to identify a particular sheet.

Signs of the Zodiac (*Astron.*) Signs named after the constellations which occupy the Zodiac, a portion of the heavens extending nine degrees on either side of the ecliptic, in which the sun and major planets perform their annual revolutions.

Silent Feed (*Eng.*) A substitute for a ratchet wheel and pawl for actuating the feeding mechanism of circular saws, etc. A form of friction clutch acts on a plain disc, the clutch gripping the disc during its forward movement and releasing it when drawn back, thus producing an intermittent rotation of the disc which is analogous to that of a ratchet wheel, but free from noise.

Silhouette. (1) A portrait or other drawing in profile, the outline being generally filled in with black; sometimes cut out from the material on which it was sketched. (2) The outline of a solid body, *e.g.* the silhouette of a range of hills: the skyline. (3) A figure cast by a shadow on a wall.

Silica (*Geol.*) Silicon dioxide in one form or another, or in combination as silicic acid with various bases, is the most important constituent in the Earth's crust. *See* SILICATES.

—— (*Min.*) A term used to include the three species Quartz, Tridymite, and Opal; though most frequently it refers to Quartz.

Silica Bricks. Firebricks composed chiefly of silica are often used in the parts of furnaces which are exposed to intense heat, but not in contact with fluxes or molten metal. *See also* BRICKS.

Silicate *or* **Slag Wool.** Slag which has been formed into fine fibres resembling wool by allowing steam to play upon a jet of molten slag; it is a good non-conductor of heat, and is used for covering steam pipes and for similar purposes.

Silicates (*Chem.*) Salts of the various silicic acids. *See* SILICON COMPOUNDS.

—— (*Geol.*) Native compounds of silicic acid with various bases. Most of them are formed in connection with either eruptive rocks or else with such metamorphic rocks as gneiss (*q.v.*) Having regard first to their mode of origin, the silicates may be grouped under three primary categories: (1) Those which are the original constituents of eruptive rocks. (2) The silicates of secondary origin which are developed in situ as a consequence of metamorphic action. (3) Silicates arising from the solution of certain minerals in one place and their redeposition, usually in the hydrated condition, in another. High temperatures and pressures prevail during the formation of the two former, and low pressures and temperatures during the formation of the last. The silicates which are of chief importance from a geological point of view are: (*a*) The Felspars and Felspathoids, which are silicates of alumina and of various alkalies or alkaline earths. Muscovite and the Micas allied to it are closely related to these. (*b*) The ferromagnesian silicates, which comprise the Amphiboles, which include Hornblende; the Pyroxenes, of which Augite is a good representative; Biotite and the Micas allied to it; and Olivine, with which may be included several closely allied species. (*c*) The Zeolites and the minerals usually classed with them. *See also* PRECIOUS STONES (III.)

Siliceous Deposits (*Geol.*) Three classes of siliceous deposits occur: (1) Those which arise directly from the tests of radiolaria or the spicules of sponges left on the ocean floor. (2) Siliceous deposits from geysers and hot springs. (3) Secondary deposits of silica, usually chalcedonic in character, due to the solution of diffused siliceous particles, such as sponge spicules, in stratified rocks, and its redeposition as chert or flint. To these might be added a fourth, which arises from the decomposition of silicates, and its redeposition at lower levels.

Siliceous Iron (*Met.*) Silica in iron produces effects analogous to those of carbon; the iron is brittle and unreliable if the silica exceeds a very small amount.

Siliceous Sinter (*Geol.*) Spongy deposits of opaline silica, deposited, largely through the action of bacteria, on the surface of the earth around the mouth of certain hot springs. These deposits, being closely associated with geysers, have been termed GEYSERITE.

Silicon (*Chem.*) Si. Atomic weight, 28·4. An element belonging to the same group as carbon in the periodic system; it can be obtained, like carbon, in an amorphous and in a crystalline form. AMORPHOUS SILICON is a maroon-coloured powder; melts only in the electric furnace; insoluble in acids, except a mixture of hydrofluoric and nitric; soluble in alkalis evolving hydrogen and forming silicates; burns in oxygen, forming silica. It is obtained by heating pure silica with magnesium powder and magnesium oxide in a fireclay crucible, and purifying the product by washing with hydrochloric acid to remove magnesium oxide, and with hydrofluoric and sulphuric acids successively and repeatedly to remove silica, and finally with water. Another form of amorphous silicon is obtained when sparks from an induction coil are made to pass either through liquid or gaseous silicon hexahydride; it reduces solutions of copper sulphate, mercuric chloride, and potassium permanganate. CRYSTALLISED SILICON: Silicon crystallises in six-sided plates or in needles; the crystallised form is more stable towards reagents than the amorphous form. It is obtained by heating silica with excess of aluminium in the electric furnace, when the liberated silicon dissolves in the metal and crystallises out on cooling; the product must be treated successively with hydrochloric and hydrofluoric acids to remove aluminium and silica.

—— (*Min.*) This element does not occur native, but in combination as the oxide, silica, it is very abundant, the anhydrous form being Quartz; the hydrous, Opal. A mixture of Quartz and Opal constitutes Chalcedony. There is a rare form of the anhydride, called Tridymite, which occurs in minute hexagonal plates. Silicon combined as silicates is very abundant; the number of different silicates known in mineralogy is over two hundred.

Silicon Compounds (*Chem.*) HYDRIDES: Silicon tetrahydride, SiH_4, is a colourless gas; boils at about $-116°$; decomposed into its elements when heated; easily takes fire in air on warming or even on sudden reduction of pressure; decomposed by caustic potash solution, $SiH_4 + 2KOH + H_2O = K_2SiO_3 + 4H_2$. It is obtained mixed with hydrogen and the hexahydride, and spontaneously inflammable by the action of hydrochloric acid on a heated mixture of magnesium and silica (magnesium silicide),

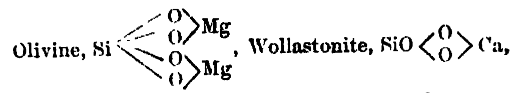
$$SiMg_2 + 4HCl = SiH_4 + 2MgCl_2.$$

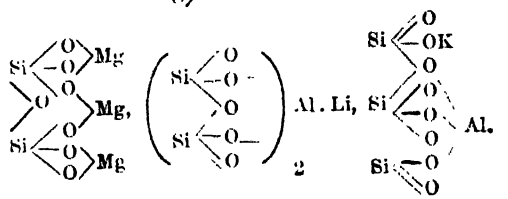
It is obtained pure by the action of sodium on ethyl orthosilicoformate,

$$4H.Si(OC_2H_5)_3 = SiH_4 + 3Si(OC_2H_5)_4.$$

SILICON HEXAHYDRIDE, Si_2H_6, is a colourless liquid; boils at 52°; it is spontaneously inflammable in air; behaves as a reducing agent. It is obtained along with the tetrahydride and hydrogen as above; the product of the reaction is cooled by liquid air when the hydrides solidify; or melting, the tetrahydride escapes. SILICIDES: Carbon silicide, CSi (CARBORUNDUM), is a colourless crystalline solid; very infusible; nearly as hard as diamond. It is made on a large scale by heating together for a long time, in a specially constructed electric furnace, glass sand, coke, sawdust, and a little salt. It is used

for grinding and boring, in steel making, and as a refractory material in the construction of high temperature furnaces. The metallic silicides are made by heating the metal and amorphous silicon together, or by heating the oxide with silica and carbon, in both cases in the electric furnace. They are hard crystalline solids, not easily attacked by reagents; but when the metal decomposes water at the ordinary temperature the silicide does so too. The silicides of the alkalis and alkaline earths yield hydrides of silicon when acted on by hydrochloric acid; *e.g.* calcium silicide is said to give silicon acetylene, Si_2H_2, with dilute hydrochloric acid; lithium silicide gives the hexahydride, and magnesium silicide acts as above. SILICON FLUORIDE, SiF_4, is a colourless gas; solidifies at $-97°$, and volatilises without melting; fumes strongly in air. It is decomposed by water to silicic and hydrofluosilicic acids. *See* HYDROFLUOSILICIC ACID. It is formed by the action of fluorine on silicon or silica, and by the action of hydrofluoric acid on silica; usually it is prepared by heating a mixture of powdered glass and fluorspar with concentrated sulphuric acid. SILICON CHLORIDE, $SiCl_4$, is a colourless liquid; boils at 59°; it fumes in air, and is decomposed by water, $SiCl_4 + 4H_2O = H_4SiO_4 + 4HCl$. It is prepared by passing dry chlorine over a very strongly heated mixture of carbon and silica. Silicon trichloride, Si_2Cl_6, boils at 146°, and begins to dissociate at 350°; the dissociation is complete at 800°; quickly heated to above 1,000°, the substance is said to be again stable. It is obtained by heating silicon in the vapour of the tetrachloride. SILICON CHLOROFORM, $SiHCl_3$, is a colourless fuming liquid; boils at 34°; very inflammable; with alcohol it forms ethyl orthosilicoformate, $H . Si(OC_2H_5)_3$. It is obtained by heating silica with powdered magnesium to obtain silicon and heating the product in a current of hydrochloric acid gas: the liquid resulting is purified by fractional distillation. SILICON OXIDE or SILICA, SiO_2, is met with in amorphous, vitreous, and crystalline forms; it is only fusible at the temperature of the oxy-hydrogen flame; it is very stable towards reagents, among acids only hydrofluoric attacks it (*see under the* FLUORIDE); alkalis attack it, forming silicates, $SiO_2 + 2KOH = K_2SiO_3 + H_2O$; a few other actions are described above. When melted it can be drawn out into threads so fine that they make excellent suspensions in physical instruments; it can also be blown like glass, and quartz vessels are much used as tubes, flasks, thermometers, because they can be heated and rapidly cooled without fear of cracking, and are less acted on than glass by many substances. Pure amorphous silica may be made from sand or any insoluble silicate by fusion in a platinum crucible with six times its weight of fusion mixture to form sodium and potassium silicates: the fused mass is extracted with water, filtered, acidified with hydrochloric acid, evaporated to dryness, and heated. There now remains a mixture of silica and sodium and potassium chlorides; the latter are extracted with water, and the silica is dried. When silica is fused it solidifies in the vitreous form. Silica occurs naturally in very many forms. Sand is often nearly pure silica; other examples are: *Crystalline:* Quartz, Amethyst, Tridymite. *Semi-crystalline:* Chalcedony, Carnelian, Agate. *Amorphous:* Flint, Chert, Touchstone. *Hydrated:* Opal, Hydrophane, Kieselgühr. SILICIC ACIDS: When a solution of sodium silicate, obtained by fusing pure silica with sodium carbonate and extracting the fused mass with water, is decomposed by hydrochloric acid, a gelatinous precipitate results if the solution is strong, but a clear liquid if the solution is weak; in the latter case, if the clear liquid be dialysed, a colloidal solution is obtained. A gelatinous precipitate is also obtained when silicon tetrafluoride is passed into water. These products have very feeble acid properties, and are compounds of silica with water. Products of the composition H_4SiO_4 and H_2SiO_3, corresponding to orthosilicic acid and metasilicic acid, have been obtained from these compounds of silica and water; but they are so unstable, changing in composition with small changes in temperature and even on exposure to air, that it is doubtful if as yet these acids have been prepared. SILICATES may be regarded as derived from orthosilicic acid and its anhydride, metasilicic acid, or from di-, tri-, etc., silicic acids, and their anhydrides. Examples:





Serpentine. Petalite—from the anhydride of disilicic acid. Orthoclase — from anhydride of trisilicic acid.

An alternative way of writing formulæ for silicates is to represent them as compounds of silica with the various metallic oxides, *e.g.* on this plan olivine would be written $2MgO . SiO_2$; orthoclase, $K_2O . Al_2O_3 . 6SiO_2$. Related elements can often in part replace each other in these silicates; in these cases the mutually replaceable elements are written in brackets. Many examples of important silicates with their formulæ written on the latter plan are given in the article on PRECIOUS STONES (*q.v.*) Many organic compounds of silicon are known.

Silk, Artificial. *See* CELLULOSE *and* WOOD PULP.

Silk Spinning and Weaving. Silk is a fine soft thread produced by the larva of the Bombycid moth, of which there are several species. The one generally cultivated, and from which the world's silk crop is chiefly derived, is the *Bombyx Mori*, or common silkworm. The eggs are about the size of a grain of mustard seed, of a bluish grey colour, and the larvæ or worms are hatched at the time of year when their natural food, the leaves of the mulberry tree, are making their appearance. About a quarter of an inch in length when hatched, the worm attains its full size, nearly three inches, in six weeks or rather more, according to the temperature in which it is reared. During this time it changes its skin four times, at each of which periods it becomes lethargic and refuses to eat. When prepared to spin, the worm selects a convenient nook or angle, and beginning at first with loose supporting threads, it gradually winds around itself an increasingly dense oval shaped ball of white or golden yellow coloured silk called the cocoon. Completing the process in three to five days, it passes into the chrysalis stage, in which it remains from fifteen to thirty days, according to climate. The chrysalis is then trans-

formed into the moth, which emerges from the cocoon by first moistening and then pushing aside the surrounding filaments. In this form it exists for a few days only, during which time the female deposits its eggs, varying from two hundred to five hundred in number. Although the moth in forcing its way through the cocoon does not eat or sever the threads, it injures the silk to some extent, and renders it difficult to reel. To prevent this the cocoons (with the exception of those intended for breeding purposes, which are carefully selected and placed aside) are subjected to treatment by heat, either in the form of steam or hot air, which destroys the vitality of the chrysalis. REELING: To reel the silk the cocoons, having been first stripped of the outward floss, are placed in a copper trough containing soft water heated to a degree sufficient to soften the natural gum and enable the thread to unwind freely. The reelable thread of the cocoons having been found, four or more ends, according to the size required, are taken and placed together, and uniting by means of the natural gum, form one thread. This passes through a succession of guide eyes, and returning to its first direction, is crossed and intertwisted on itself, causing a pressure which condenses the filaments into a compact, round, smooth thread, which passes on to a revolving reel. Great care is required to rapidly replace a filament should one break or run out, this being done not by a process of tying, but by simply attaching it to the thread in motion, to which it adheres by reason of its wet, gummy condition. Crude methods and carelessness in reeling are responsible for the inferiority of the bulk of Asiatic as compared with European silks; but the "FILATURE" SILKS of China and Japan, so called when reeled by European machinery and methods, cannot be excelled for beauty and evenness. THROWING: The reeled thread, termed "RAW SILK," is received by the throwster in large hanks. It is first divided into smaller hanks, then sorted into grades of size and wound on bobbins. It is again rewound on other bobbins, the thread passing through a cleaner, a narrow opening between two blades sufficiently large to allow the passage of the thread, but stopping its progress when lumps or nibs present themselves. If for ORGANZINE, the bobbins, which are made to revolve, are placed in an upright position in a spinning machine, the thread is conducted through an eye, wound round an upright wire two or three times to give tension, and in passing on to another bobbin, receives usually about fifteen twists or turns to the inch. These bobbins then pass to the doubling frame, are again placed in an upright position, but do not revolve, the threads being taken from them by means of an eyelet at the end of a revolving wire, usually two, but sometimes three, threads passing together on to one bobbin. The bobbins containing the double or trebled thread are then placed in the throwing machine and wound off into skeins, either for ordinary or for Grant reel, the thread receiving a certain number of turns per inch, according to the fabric for which the silk is intended—about eleven turns if for satin faced fabrics, more if for crêpe, gauze, umbrella silks, or other fabrics where the warp threads are subjected to much friction in the process of weaving. For TRAM the singles get no twist; the reeled thread is wound and then doubled, receiving only a slight spin. After throwing, the skeins are weighed, and the length of the skein being known, the size of silk is determined by the weight of each skein according to length. The term "silk spinning" is also used in connection with the utilisation of the waste silk made in reeling, winding, and throwing. Fully 30 per cent. of the produce of the silkworm can only be treated by this method. The waste silk is combed into short lengths or drafts from 2 to 6 in. in length. The ends are laid carefully over each other and, passing through a series of combs and over a drum, are drawn out into a lap of about 2 yards in length. These lengths are again laid continuously over each other, and passed over rollers and through combs, being drawn out eventually into a sliver or tape of several hundred yards. After this treatment the spinner is able to pass the silk on to a bobbin by the roving process, as generally employed in cotton spinning. The subsequent processes correspond very nearly to those used in cotton or wool manufacture. WEAVING: With the exception of a few fabrics woven in the grey or gum state, silk is dyed in the skein before weaving. It loses about 25 per cent. of its weight if dyed "soft" or "bright," by the extraction of the natural gum in boiling off, and about 12½ per cent. if dyed "souple." There is no loss if dyed "hard." It is then wound on bobbins, the organzine being warped into the required length and count, and afterwards spread upon the cane or warp roll by a process called "beaming." In low counts warped by power, the warping mill is dispensed with, the silk passing direct from the creel on to a drum from which it is beamed. The warp is then placed in the loom, and the threads "entered" or passed one by one through the loop or eye of the shaft in plain, or of the maille in figured harness, and afterwards drawn in sections through the interstitial spaces of the reed. In the case of a harness through which a cane has just been finished, the new warp is joined thread by thread by a process of "twisting" to about a yard length of the previous warp left in it, termed a "thrum." The art of weaving in its most primitive state consisted of picking up the warp threads with the fingers and interlacing them with the weft, but as science advanced the idea was conceived of raising a section of the warp by means of a heddle, thus obtaining a shed or opening for the weft to pass through, and it is at least probable that the weaving of linen and woollen cloths by the latter method was practised by the ancients ages before they had any knowledge of the possibility of spinning a weavable thread from the product of the silkworm. The plain HAND LOOM, which still retains much of its original simplicity, is a wooden structure consisting of four posts so placed as to form a rectangle, and framed together at top with beams. It is usually about 6 ft. in height, 6 ft. 6 in. in length, and 4 ft. 6 in. in width for cloth 36 in. wide or less. At one end, supported in clamps attached to the posts, the warp roll is placed; at the opposite end is the cloth beam or breast roll on which the woven silk is wound, the harness is placed about 15 in. from the breast roll and suspended from levers (termed TUMBLERS or TIPLERS) at the top of the loom, and attached by cords to other levers beneath, called long and short lames. Between the harness and the breast roll is the batten carrying the reed. The shed is obtained by the weaver pressing his feet alternately on treadles which, acting upon the harness, raise certain heddles whilst depressing others; simultaneously with such action he pushes back the batten with one hand, throwing the shuttle through the shed with the other, the return action of the batten causing the reed to beat up the weft to the required number of picks per inch. In many narrow works, and always where the fabric exceeds

36 in. in width, the fly batten is used. In figured weaving, a mounture or figured harness replaces or supplements the plain harness. The working of this was at one time a slow, laborious method, requiring in addition to the weaver who raised the ground harness and threw the shuttle a lad called a "draw boy," who worked a machine at the side of the loom and obtained the shed for the figure by drawing in their required order of succession lashes attached to the mounture cords. The arranging of the lashes and cords for a particular pattern was a long and expensive operation frequently occupying many months before weaving could begin. A great revolution in figure weaving was effected by J. M. Jacquard, of Lyons, who in 1801 patented a machine which, placed on the loom and attached to the mounture, enabled the weaver to obtain the shed for figure and ground together, thus dispensing entirely with the services of the draw boy. Its action is controlled by perforated cards, laced together in an endless band, which pass over a cylinder and act in succession on the points of a set of horizontal wires called needles, connected with which are perpendicular hooks attached to the neck cords of mounture. Where the cards are perforated, the needles stand forward, enabling metal blades called the griffe, when raised by weaver depressing the treadles, to catch corresponding hooks, thus drawing up the warp threads in mounture and creating the shed. Simultaneously with the shedding motion the pressure of the card on the needles is removed, allowing the latter where driven back by the blank spaces in the cards to be returned to their position by means of small brass springs placed behind them. With the return of the griffe a fresh card is brought to bear on the face of the needles. The Jacquard for silk weaving usually contains 408 or 612 hooks, needles, and springs, the number of possible perforations in the cards corresponding. The POWER LOOM, the invention of which dates back to 1785, was not adapted to any extent to the weaving of silken fabrics until many years later, it being thought that silk, owing to its fine delicate texture, could only be successfully and profitably dealt with by the hand loom weaver. Constant improvements, however, in the various parts of the mechanism, particularly of the shedding and picking motions, in the manipulation of the warp, the adaptation of improved Jacquards and swivel battens for figured fabrics, have rendered the up-to-date power loom capable of weaving the most beautiful and elaborately figured, as well as the simplest, plain silks to perfection, and with the exception of a few exceedingly rich qualities, of which only short lengths are required it has superseded the hand loom. The mechanism of the power loom comprises various makes and patents, many of them equally good, but the motions they control are essentially the same as in the hand loom, *viz.* (1) the creation of the shed by the raising and depressing of certain heddles in plain weaving, or by the raising of certain hooks of Jacquard in figured weaving; (2) the propelling of the shuttle carrying the weft through the shed; (3) the beating up of the weft by means of the reed carried in the batten; and (4) the taking up of the cloth when woven. The construction of the power loom is more compact than the hand loom, the warp roll is placed much nearer the harness, no long porry being required for picking and cleaning the silk, this having been done before the warp is placed in the loom; the batten instead of swinging from the loom top is attached to and works on a pivot at the base of the loom, the shuttle race and reed being thus at the top of the batten. The shuttle is much larger and heavier than used in hand loom, giving steadiness when running at a hundred and fifty or more picks a minute, and by accommodating a large pirn or bobbin, enables the loom to run for a longer period without stopping for renewal of supply of weft. A delicately adjusted weft fork, placed between the shuttle box and edge of cloth, feels for the weft thread at each pick as it enters the shuttle box, stopping the loom should it break or run out. The SHED is obtained by the following motions: The tappet or eccentric for the simplest form of plain cloth, the dobbie for other plain cloths such as twills, satins, checks, etc., the Jacquard for figured weaving. The cloth when woven is wound on cloth roll by a set of change wheels of different sizes, which by careful adjustment take up the cloth and regulate the number of picks required, a compensating appliance acting on batten keeping the cloth of an even thickness when weft is irregular. Silk fabrics, with the exception of those having a pile surface, such as velvet or terry, are woven face downwards.—F. W.

Sill (*Build.*) (1) The lowest horizontal member of a window, door frame, partition, etc. (2) The stone at the bottom of a window or a door opening.

—— (*Civil Eng.*) The horizontal member forming the floor, or lowest margin of the opening, of dock gates, etc.

—— (*Geol.*) A term now generally applied to an intrusive sheet of eruptive rock, such, for example, as the Whin Sill of the North of England. It differs from a Laccolite (*q.v.*) in the fact that a Sill does not occupy the position of a bedding plane.

—— (*Mining*). (1) The floor of a gallery or passage. (2) A flat mass, ledge, or surface; in particular, a flat mass of hard rock.

Sillimanite (*Min.*) *See* ANDALUSITE.

Silo. *See* ENSILAGE.

Silurian System (*Geol.*) A name applied to the great group of marine sediments which lie between the Devonian Rock on the one hand and those of Ordovician Age on the other. As now classified in accordance with the nature of their fossil contents, they consist of (1) the Downtonian Rocks, below which are (2) the Salopians, which in their turn overlie the Valentian Rocks. In Westmorland their aggregate thickness is fully 12,000 feet.

Silver (*Chem.*) Ag. Atomic weight, 107·9. A white metal; crystallises in regular forms, such as the cube and octahedron; melts at 961°; boils at 2,050°; very malleable and ductile, capable of taking high polish; the best conductor of heat and electricity. Very thin films transmit blue light. Melted silver dissolves oxygen; 1 volume silver dissolves about 20 volumes oxygen; on solidifying it gives up the dissolved oxygen, and this gives rise to the "spitting" of silver, the escaping oxygen raising the solidified surface of the metal into fantastic shapes. Silver is not oxidised in air at the ordinary temperature nor on heating, but on heating in oxygen at 300° under a pressure of 15 atmospheres it is oxidised to the extent of 50 per cent.; it unites with the halogens directly; sulphuretted hydrogen and aqueous solutions of the alkaline sulphides convert it into sulphide,

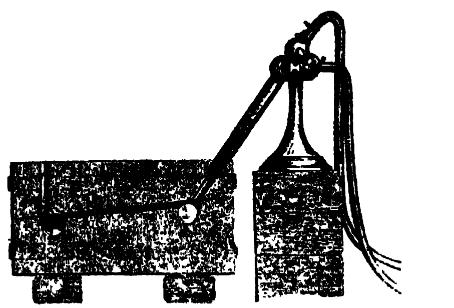
$$2Ag + Na_2S + 2H_2O = Ag_2S + 2NaOH + H_2.$$

Hydrochloric acid has no action, but hydrobromic and especially hydriodic acid dissolve it with liberation of hydrogen, probably owing to the

solubility of silver bromide and iodide in the respective acids. Hot strong sulphuric acid gives silver sulphate and sulphur dioxide. Nitric acid dissolves it readily. *See* NITRIC ACID. Allotropic forms of silver are said to be produced when silver solutions are precipitated by various reducing agents, *e.g.* when silver nitrate is precipitated with ammonia iron citrate. These precipitates vary in colour from blue black to red. When dilute silver nitrate is reduced by hydrazine hydrate, a green form is obtained in solution. By passing the electric arc between silver poles under water a reddish brown liquid is formed. (*See* ENZYMES.) None of these forms of silver has been obtained pure, and the "solutions" are probably "suspensions" only. Silver sometimes occurs native; more commonly as Argentite (*q.v.*), Pyrargyrite (*q.v.*), Polybarite (*q.v.*), Horn Silver (*q.v.*) Many different processes are employed to extract silver from its ores: (1) MEXICAN AMALGAMATION PROCESS. The ore consists chiefly of silver and silver sulphide. The process is worked where steam and water power are not available. The wetted ore is ground between blocks of porphyry turned by mules; mixed on a paved floor (patio) with common salt by the trampling of mules; mercury and a substance known as magistral (copper pyrites roasted so as to make copper sulphate) are added, and these things well trampled in; more mercury is added, and the trampling continued; but the charge (torta) is also turned from time to time with shovels; the trampling goes on till the requisite amount of mercury is amalgamated. This may take some days. The mass is now washed with water in large vats provided by stirrers worked by mules The amalgam is filtered through canvas, pressed, and distilled, when mercury passes over and silver is left behind. A recent explanation of the changes is that cuprous chloride is formed by double decomposition between cupric sulphate and salt and reduction of the cupric chloride by mercury; the cuprous chloride then acts as an oxygen carrier.

$Cu_2Cl_2 + 4O + Hg + Ag_2S = Cu_2Cl_2 + HgSO_4 + 2Ag.$

This explanation is offered because silver chloride is difficult to work by this process, and it is never found in the torta, and the author (Ortega) uses copper hypochlorite in place of cuprous chloride, which is much quicker in its action. (2) Where steam power is available the WASHOE AMALGAMATION PROCESS is commonly used. In this the ore is first well crushed with water, then ground to a fine pulp in iron pans with water and mercury, common salt and copper sulphate being added if desirable; also, if the ore contains sulphide, sodium is added to the mercury to prevent formation of mercuric sulphide; the pulp is washed by agitating it with water, this allowing the amalgam to settle, while earthy impurities are washed away; excess of mercury is removed by pressing the amalgam in canvas bags, and then the amalgam is distilled in iron retorts, the silver remaining behind in the retort. The crude silver is melted and stirred with iron rods, so that oxidisable metals are removed—some oxides, such as those of antimony and bismuth, volatilising, while others, such as copper and lead, form a scum on the silver which can be skimmed off. A considerable amount of silver is obtained from burnt pyrites. (*See* COPPER.) From the precipitated iodide the silver is easily obtained by reduction with zinc and hydrochloric acid. Galena usually contains silver, and from the argentiferous lead obtained from galena the silver is extracted by Parkes' process. (*See* LEAD.) COMMERCIAL SILVER is always impure. To obtain CHEMICALLY PURE SILVER many processes are available. Stas, in his atomic weight determinations, employed half a dozen distinct methods, and also distilled silver. The first pure silver he had was prepared by reducing a 1 per cent. solution of silver nitrate by allowing finely divided phosphorus to stand in it; the metal, after standing some time in excess of a silver nitrate solution and being digested with aqueous ammonia, was fused with borax and nitre; it was quite pure. Another method which he used on a large scale, and which gave metal of "extraordinary purity," was to dissolve silver in boiling dilute nitric acid, evaporate to dryness, and melt. On cooling, the nitrate was dissolved in ammoniacal water and allowed to stand, then filtered and diluted till it contained not more than 2 per cent. of silver; then a solution of normal ammonium sulphite (prepared by passing sulphur dioxide into ammonia) was added in quantity such that on warming a portion of the mixture no blue colour remained, and the whole allowed to stand forty-eight hours in a well stoppered vessel; this precipitated one-third of the silver, and the rest is precipitated on heating at 60° to 70°; the precipitate was washed with ammoniacal water till the washings neither turned blue on standing in air nor gave a precipitate with barium chloride; the metal was then left standing a day or two under concentrated ammonia, and finally washed with pure water. To get it in bar form it was melted in an unglazed porcelain crucible with 5 per cent. of its weight of burnt borax, to which 10 per cent. of sodium nitrate had been added. Stas distilled considerable quantities of his pure silver in the arrangement shown in the figure. The block is of burnt white marble held together with iron bands, and is in two pieces, as shown by the sloping line; it is 25 to 30 cm. long and 10 cm. wide, and total height 15 cm.; the right hand hole admits the jet of



an air coal-gas blowpipe to the roughly spherical cavity which serves as retort; the opening connecting retort to receiver is 0·5 cm. high and as wide as the diameter of the retort (3 cm.); the receiver communicates with a vertical opening for escape of uncondensed vapour. The silver distils over in 10 to 15 minutes, and the retort, examined by a lens, shows no trace of a residue. PURE SILVER is not used for any ordinary purposes on account of its softness. The silver used for ORNAMENTAL ARTICLES and for the coinage is alloyed with copper; the hardest alloy contains 4 parts of silver to 1 part of copper. STANDARD SILVER is the silver used for coinage, and it consists of 925 parts of silver to 75 parts of copper. The FINENESS of any other silver is expressed in terms of standard silver by stating the number of pennyweights per pound troy of copper by which it exceeds or falls short of

standard silver; thus 240 dwt. (1 lb. troy) of standard silver contain 18 dwt. copper, and the hard alloy mentioned above (4 parts silver to 1 part copper) contains in 240 dwt. 48 dwt. of copper, so their alloy would be referred to as "worse 30 dwt." "OXIDISED SILVER" is silver which has been superficially coated with silver sulphide by dipping it in potassium sulphide solution. Besides its use in making silver articles and coins, much silver is used in ELECTROPLATING (*q.v.*) and in making mirrors. For SILVERING GLASS many recipes are available. A simple one is: Dissolve 8 grams of Rochelle salt in 3·84 litres of water; boil, and while rapidly boiling add a solution of 10 grams silver nitrate in 80 cc. water; allow to cool and then filter. Now dissolve 10 grams of silver nitrate in 80 cc. water, add ammonia till the precipitate of silver oxide is barely all dissolved, make up to 960 cc. Care being taken that the glass to be silvered is scrupulously clean, it is put in a sufficient quantity of a mixture of equal volumes of each of the two solutions at a temperature of about 20° to 21°. The world's production of silver in 1903 amounted to about 5,800 tons, and by far the greatest part of it was extracted in Mexico and the United States. W. H. H.

Silver (*Min.*) This element occurs native in octahedral crystals belonging to the cubic system. More often it is in filiform masses of silver white colour when fresh, but often tarnished to a black, green or yellow colour. The mineral is sectile, flexible, and ductile. It usually contains traces of copper, gold, platinum, etc. It has been found in Cornwall; more abundantly at Kongsberg in Norway, in Saxony, Bohemia, Hungary, France, Siberia, and in quantity in Central and South America. The element also exists in many other minerals, the chief of which are Argentite, Stephanite, Pyrargyrite, Proustite, Horn Silver, Polybasite, and Freieslebenite (*q.v.*)

Silver Amalgam (*Min.*) *See* AMALGAM.

Silver Compounds (*Chem.*) SILVER OXIDE, Ag_2O, a brownish-black powder; begins to decompose at 250°, and is completely decomposed at 300°; slightly soluble in water (6·5 grams in 100,000 cc. water at 20°), this solution having an alkaline reaction. When moist it reacts as an alkali (AgOH), precipitating hydroxides from many salt solutions and replacing halogens in many organic compounds by hydroxyl groups; *e.g.* tetramethylammonium iodide with moist silver oxide gives tetramethylammonium hydroxide:– $N(CH_3)_4I$ gives $N(CH_3)_4OH$. It dissolves readily in ammonia, and the solution contains the powerful base $Ag(NH_3)_2OH$, which is ionised to $Ag(NH_3)_2{}^{I}$ and $(OH)^{I}$. This solution, on standing exposed to air, deposits the black explosive fulminating silver NAg_3. Silver oxide is prepared by precipitating a solution of silver nitrate with a solution of caustic potash, filtering, washing, and drying the product at 60° to 80°. When a solution of silver nitrate is electrolysed, black crystals are deposited on the anode; these appear to be a compound of a higher oxide of silver with silver nitrate, and have been called silver "peroxynitrate"—probable formula $2Ag_3O_4 . AgNO_3$. SILVER CHLORIDE, AgCl, a white solid; melts at 450°; volatile at a white heat, giving vapour density 80 at 1700°; very slightly soluble in water, 100 cc. solution contain ·000153 gram at 20°; more soluble in hydrochloric acid (1 in 200 of the concentrated acid); it is very soluble in ammonia, potassium cyanide, and sodium thiosulphate solutions, forming soluble double compounds—*viz.* $2AgCl3NH_3$ (also formed by passing ammonia gas over dry silver chloride), $NaAgS_2O_3$, $KAg(CN)_2$. Silver chloride is blackened on exposure to light under ordinary conditions, but not when exposed in dry oxygen or in a vacuum; the blackening is prevented by chlorine water and by ferric chloride solution—substances which can give up chlorine. The explanations offered are (1) that an oxychloride is formed, (2) that a subchloride, Ag_2Cl, is formed. If either of these explanations is correct, it is strange that compounds of these formulæ cannot be prepared artificially. Silver chloride is reduced to the metal by hydrogen, (*a*) when heated in hydrogen—a reversible reaction; (*b*) when in contact with zinc and a dilute acid, such as sulphuric or hydrochloric. It is completely converted into bromide by digesting it with a solution of potassium bromide, and into iodide by potassium iodide. Silver chloride can be prepared by passing chlorine over heated metallic silver, or by precipitating a solution of silver nitrate by hydrochloric acid or a soluble chloride. SILVER BROMIDE, AgBr, a white or yellow solid, according as it is obtained by precipitation of excess of silver nitrate by potassium bromide or by adding excess of the latter to silver nitrate; melts at 429°; nearly insoluble in water; 100 cc. solution contain ·0000084 gram at 20°; soluble in hydrobromic acid, from which it can be crystallised; soluble in strong ammonia; decomposed by chlorine; converted into iodide by digesting with potassium iodide solution. This salt is largely used in preparing photographic plates, owing to the extreme sensitiveness of silver bromide to the action of light. What the action of light is does not appear to be known. SILVER IODIDE, AgI, is a pale yellow solid; melts at 530°; its behaviour on heating is abnormal, as it contracts on heating to 70°, and expands on cooling again, probably owing to a change of form; when pure it is not acted on by light; very slightly soluble in water; 100 cc. solution contain ·000053 grams at 20°; slightly soluble in ammonia; soluble in hydriodic acid and in strong potassium iodide, forming the compounds $HAgI_2$ and $HAgI_3$. It is easily decomposed by chlorine; it is reduced by zinc and dilute hydrochloric or sulphuric acid to the metal. Silver iodide is obtained by precipitating silver nitrate solution by potassium iodide solution; by dissolving silver in hydriodic acid, and from either the bromide or chloride by digesting them with solution of potassium iodide. SILVER NITRATE, $AgNO_3$ (also called LUNAR CAUSTIC); white rhombic plates; often met with cast in sticks; melts at 198°; very soluble in water; 100 cc. water dissolve 227·3 grams at 19·5°. Decomposes when strongly heated, leaving behind metallic silver and giving off nitrogen peroxide, oxygen, and nitrogen; with ammonia in excess it forms the compound $AgNO_32NH_3$, which crystallises out on allowing the solution to evaporate, and exists in solution ionised into $Ag(NH_3)_2{}^{I}$ and $NO_3{}^{I}$ (*cf.* SILVER OXIDE); dry silver nitrate absorbs ammonia gas and forms the solid $AgNO_33NH_3$, with evolution of much heat. It is rapidly reduced to metallic silver (black) by organic matter, especially in presence of light. Hydrogen slowly reduces it to the metallic state. Silver nitrate is made by dissolving silver in nitric acid, evaporating to dryness, fusing, and recrystallising from water. It is employed in preparing other silver salts; in medicine for cauterising; as a hair dye. SILVER NITRITE, $AgNO_2$; a white crystalline powder; sparingly soluble in water; used in the preparation of pure alkaline nitrites and of fatty nitro-compounds. It is prepared by mixing warm solutions of silver nitrate and

potassium or sodium nitrite. SILVER SULPHATE. Ag_2SO_4, is a white crystalline solid, sparingly soluble in water: 100 cc. water dissolve ·58 gram at 18°; it is made by dissolving silver in hot concentrated sulphuric acid; occasionally used as a reagent. SILVER CYANIDE, AgCN, a white solid, very slightly soluble in water; 100 cc. solution contain ·000022 gram at 20°; decomposed on heating into silver and cyanogen; heated with sulphur, it forms the sulphocyanate AgCNS; it is soluble in ammonia and in potassium cyanide solutions, forming the compounds $AgCN.NH_3$ and $KAg(CN)_2$: the latter is a white crystalline solid, which is much used in the electrolytic deposition of silver. Silver cyanide unites with alkyl iodides when these are heated together in sealed tubes with a little ether, and the product yields alkyl isocyanide when distilled with potassium cyanide: $C_2H_5I + 2C_2AgCN = C_2H_5Ag(CN)_2 + AgI$ $C_2H_5Ag(CN)_2 + KCN = C_2H_5NC + KAg(CN)_2$. Silver cyanide is made by adding potassium cyanide solution to a solution of silver nitrate. Silver forms salts with all organic acids, and the great majority of these organic silver salts are insoluble in water. On being heated in air they decompose, leaving a residue of silver. In virtue of this property they are used to determine the molecular weights of organic acids, for it is obvious that if the basicity of the acid is known to be n, and a grams of the normal silver salt on heating leave behind b grams of silver, then

$$\frac{\text{Molecular weight of silver salt}}{108\,n} = \frac{a}{b}.$$

$$\therefore \text{Molecular weight of acid} = \left(\frac{108a}{b} - 107\right)n.$$

Silver Glance (*Min.*) *See* ARGENTITE.

Silver Grain (*Carp., etc.*) The grain or markings in timber due to the medullary rays (*q.v.*) Oak cut so as to display the silver grain to advantage is termed WAINSCOT OAK.

Silvering. Coating an object with silver either by chemical deposition or by electrolytic methods. *See* ELECTROPLATING.

Silver Lead Ore (*Min.*) Galena containing a sufficient quantity of silver to make it profitable to extract the silver. The amount of silver in the ore varies from mere traces up to 3 per cent. When silver was at a higher price, an ore containing three ounces of silver to the ton paid for extraction by the Pattinson process.

Silver Leaf (*Dec.*) When used by sign writers and decorators consists of pure silver reduced to sheets; applied in the same manner as gold leaf. It must be protected by a coating of lacquer or varnish, or it will turn black. Aluminium leaf, which does not change colour, is now usually employed instead of silver.

Silverplating. *See* ELECTROPLATING.

Simile (*Music*). In the same manner. When a figure is to be repeated, instead of writing the passage again, simili marks are put thus // or ·/· (*cf.* "And lo!" and "And suddenly," in Handel's *Messiah*).

Simoon (*Meteorol.*) A term applied to the hot suffocating winds laden with dust and sand which are peculiar to the sandy deserts of Africa and Western Asia.

Simple Harmonic Motion (*Phys.*) *See* HARMONIC MOTION.

Simple Machines. The term used in theoretical mechanics to denote the Levers, Pulleys, Wheel and Axle, Inclined Plane, and Screw. They are often called the MECHANICAL POWERS, but the term is not a good one, and should be avoided.

Simple Microscope (*Light*). A single lens used for producing a magnified virtual image of an object placed close to the lens: a magnifying glass is therefore a simple microscope.

Simple Pendulum (*Phys.*) *See* PENDULUM.

Simpson's Rule. A useful rule for the measurement of the areas of irregular plane figures. The area is divided into strips by parallel and equidistant lines or ordinates. The length of each of these ordinates and their distance apart is measured; then the total area is the product of the ***distance apart × half the sum of the first and last ordinates, + the sum of the remaining ordinates.***

Sin. SINE: *see* TRIGONOMETRICAL RATIOS.

Sinapine (*Chem.*) *See* MUSTARD OILS.

Sine (*Math.*) *See* TRIGONOMETRICAL RATIOS.

Sine Curve. *See* SINES, CURVE OF.

Sine Galvanometer (*Elect.*) *See* GALVANOMETERS.

Sines, Curve of (*Math.*) A curve showing the ratio between an angle of given value and its sine. An example is given under Harmonic Motion (*q.v.*)

Singeing (*Textile Manufac.*) The process of passing the thread during the final spinning or doubling through jetted flames of gas. If applied to the yarn, also termed "gassing." Fabrics in which mohair yarn is used for the weft are singed over hot rollers. *See* GASSING.

Singing Flame (*Sound*). A jet of hydrogen and certain other gases when burnt under the mouth of a tube open at both ends will often set up a loud note.

Single Acting Engine (*Eng.*) An engine in which the impulse is given on one side of the piston only; they include nearly all the ordinary forms of gas, oil, and petrol engines, and a number of high speed steam engines, such as those of Willans, Brotherhood, and Mather and Platt. *Cf.* STEAM ENGINES.

Single Acting Piston (*Eng.*) The piston of a single acting engine; it is commonly made in the form of a short cylinder closed at one end and having the connecting rod hinged to a gudgeon pin within it. This forms what is sometimes termed a TRUNK PISTON. *See* GAS ENGINE *and* PETROL ENGINE.

Single Belt (*Eng.*) A driving belt composed of one thickness of leather.

Single Cylinder Machine (*Paper Manufac.*) A paper machine provided with one very large drying cylinder instead of the usual twenty or thirty.

Single Ended Boiler (*Eng.*) A ship's boiler having a grate at one end only.

Single Fished Joint (*Eng.*) A joint with one fishplate (*q.v.*)

Single Floor (*Carp. and Join.*) A floor consisting of one set of joists, to which the floor boarding and ceiling are fixed. *See* FLOORS.

Single Flue Boiler (*Eng.*) A CORNISH BOILER. *See* BOILERS.

Single Fluid Hypothesis (*Elect.*) *See* ELECTRICITY.

Single Geared Lathe (*Eng.*) A lathe without back gear (*q.v.*)

Single Phase Current (*Elect.*) An ALTERNATING CURRENT (*q.v.*) of the ordinary kind.

Single Riveting (*Eng.*) A lap joint is single riveted when there is one row of rivets only; a butt joint when there is one row on each side of the joint.

Singles (*Eng.*) Sheet iron intended for tinning.

Sinister (*Her.*) The sinister or left hand side of a shield. It must be remembered that this refers to a shield, as it was held to protect the body; to the spectator from the front the sinister side is on his right hand.

Sinking (*Build.*) A recess; any part below the general surface of an object.

Sinking Pump (*Civil Eng.*) A pump which can be lowered into a shaft or other deep excavation until it is sufficiently near the bottom to draw up water into its barrel.

Sinks (*Sanitation*). By a model bye-law of the Local Government Board the waste pipe from every sink must discharge in the open air over a channel leading to a trapped gully at least 18 in. distant. The waste pipe should be provided with a siphon trap fitted with a screw cap, which can be removed for the purpose of cleansing the trap. *See* SIPHON TRAP; TRAP; *and* SEAL.

Sinople (*Her.*) Vert. *See* HERALDRY.

Sinter *or* **Geyserite** (*Min.*) *See* SILICEOUS SINTER.

Sinusoidal. Having the form of a sine curve (*q.v.*)

Siphon. A bent tube with arms of unequal length, used for drawing a liquid out of a vessel. The shorter arm dips into the liquid, while the other arm overhangs the containing vessel in such a way that its end lies below the level of the liquid. If the tube be first filled with the liquid, which is prevented from escaping while the tube is being placed in position, the liquid will commence to flow through the siphon, and will continue to flow so long as the shorter arm dips into, and the outer end is below the level of the liquid in the vessel. The siphon may be placed in position when empty, and started by drawing the liquid up into the tube by suction applied to the longer limb.

Siphon Barometer (*Meteorol.*) A form of barometer the tube of which is in the form of a siphon. There are three main classes of barometers, SIPHON, CISTERN, and ANEROID. *See* BAROMETER.

Siphon Recorder (*Elect. Eng.*) A form of telegraphic recording instrument in which the symbols are produced on a moving strip of paper by a fine jet of ink, flowing from a light glass tube bent so as to form a siphon. One arm of the latter dips into a reservoir of ink, while the other end can be moved backward or forward through a small distance by the action of the transmitted current.

Siphon Trap (*Sanitation*). This consists of a pipe curved somewhat like the letter S, the lower bend being intended to retain sufficient water to reach above the level of the upper side of its curve. The water so retarded forms a "water seal," and prevents the entry of sewer and other gases from the drains. In the case of sink discharge pipes, a screw cap or CLEANING EYE is fitted at the lowest point of the bend, and can be removed for cleansing the trap. *See* SEAL *and* TRAP.

Siren (*Sound*). A piece of apparatus for investigating the pitch of a note or the relation of pitch to frequency. A rotating plate is pierced with holes bored at equal distances along the circumference of a circle on the plate. On causing an air jet to impinge on the row of holes, a note is produced whose frequency is proportional to the number of holes which pass the jet in one second. The number of revolutions of the plate is registered by some form of counting mechanism, and hence the total number of vibrations per second which corresponds to the particular note observed can be determined. Very large sirens are commonly used in factories and on steamships to emit a loud note as a signal or warning, *i.e.* to serve as foghorns.

Sirocco (*Meteorol.*) A hot moist wind, receiving its heat from the Sahara and its moisture from its passage northward over the Mediterranean. Met with in Sicily, South Italy, and adjoining districts.

Sisal Hemp (*Botany*). A fibre largely used in ropemaking. It is obtained by maceration of the leaves of the American aloe, *Agave rigida* (order, *Amaryllidaceæ*).

Sistrum (*Archæol.*) An instrument of the character of a rattle, especially associated with the worship of the Egyptian goddess Isis. It consisted of metal rods fitting loosely in an oval-shaped metal frame, the ends of the rods being bent up to prevent them from slipping out.

Sites (*Hygiene*). The following considerations should, if possible, be taken into account in the choice of a building site: (1) The nature of the Soil (*q.v.*) (2) The aspect, as regards wind, light, air. (3) The surroundings, as, for example, the neighbourhood of trees or hills. The distance of the ground water from the surface is an important factor in the healthiness of a site; it should never be less than 10 ft., and, if possible, at least 15 ft. or 20 ft. from the ground level. As regards aspect, other things being equal, an east or south-east aspect is to be preferred, so as to secure the maximum amount of sunlight both on the front and back of the house. Valleys lying in the direction of the prevailing winds are healthier than those lying in other directions. The neighbourhood of trees is desirable, provided they do not obstruct the light and air. Rising ground facilitates the natural drainage both of the surface and of the subsoil. *See* SITE AND STRUCTURAL ARRANGEMENT OF HOUSES *under* SANITATION.

Sitting (*Art*). The period during which a person sits for a portrait, or during which a model poses. The uninterrupted period during which an artist works.

Six-Part Vaulting (*Architect.*) *See* SEXPARTITE VAULT.

Six's Thermometer (*Heat*). *See* MAXIMUM AND MINIMUM THERMOMETER.

Sixteenmo (*Print.*) A sheet printed so as to form 16 leaves (32 pages) when folded. Abbreviation, 16mo.

Sixth (*Music*). The interval of two notes alphabetically six letters apart, as D to B. *See* INTERVAL.

Sixty-four-mo (*Print.*) A sheet which when printed is folded so as to form 64 leaves (128 pages) of a book, the size of each leaf being about $2\frac{1}{4}$ by $3\frac{1}{2}$ in. A book of this size.

Size. Glue or other gelatinous material which has been allowed to absorb a considerable quantity of water, thus forming a soft and homogeneous jelly.

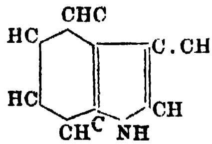
—— (*Bind.*) (1) A preparation consisting of a thin solution of glue or paste wash applied to bindings previous to finishing and gilding. (2) A

solution of gum tragacanth or gum dragon used for floating the colours in marbling (*q.v.*)

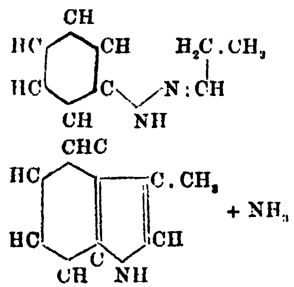
Sizing. The process of treating a surface or a substance with a suitable size (*q.v.*)

—— (*Textile Manufac.*) The application of a glutinous liquid to the warp yarn for the purpose of increasing the adhesiveness of the fibres and strengthening the threads for weaving. In cotton manufacture the warp yarns are passed through a size mixture composed of flour, tallow, soap, etc. *See* SLASHER SIZING *and* LINEN MANUFACTURE.

Skatole (*Chem.*)



(Scatole: β-methylindole). White shining plates; melts at 95°; boils at 266° (755 mm.); it has a strong fæcal odour, and occurs in fæces; it is sparingly soluble in cold water, much more soluble in hot water; soluble in alcohol, ether, light petroleum. It gives the pine-shaving reaction (*see* PYRROLE) but only when the shaving is dipped in a hot alcohol solution, and then put into concentrated hydrochloric acid. It gives a picrate (red needles). It gives a nitroso compound with nitrous acid. Skatole always occurs in fæces; it is sometimes present in urine combined with sulphuric acid. Skatole is formed in the putrefaction of proteids, *e.g.* egg-albumin, and when proteids are fused with caustic potash. It is also formed from indigo by reducing it with tin and hydrochloric acid, and distilling the product with zinc dust (when prepared in this way it does not smell of fæces). It is prepared synthetically by heating the phenyl hydrazone of propionic aldehyde with zinc chloride (its own weight): the reaction begins without the aid of heat, but toward the end it is heated to 180° for a minute.



The product is distilled in steam, and the distillate extracted with ether. Skatole is used to some extent in making artificial perfumes.

Skean, Skein (*Arms*). A double-edged dagger or sword peculiar to the ancient Irish race.

Skean-dhu (*Arms*). The knife or dagger worn by Scottish Highlanders in the stocking.

Skeleton. Framework which constitutes the chief supporting parts of a structure, *e.g.* a series of iron bars on which a plaster cast is built up.

—— (*Zool.*) The framework supporting the body of an animal; it consists of (1) connective tissue; (2) cartilage; (3) bone. The internal structure usually termed the skeleton is distinguished in zoology as the ENDOSKELETON; in addition to this, or in place of it (in the case of invertebrates) there may also be an EXOSKELETON, a hard external structure serving to support the body.

Skeleton Drums (*Paper Manufac.*) Light cylindrical frames constructed of wood, used in drying "tub sized" papers.

Skeleton Form (*Typog.*) A form (*q.v.*) of a light or open character, consisting either of rules to form boundaries and columns for table matter or of odd lines to be printed in a second colour.

Skeleton Frame (*Join.*) Wooden framing of any description, without panels.

Skeleton Girder (*Eng.*) A LATTICE or openwork girder (*q.v.*)

Skeleton Pattern (*Foundry*). A pattern whos form follows the main outlines of the casting, the remainder of the mould being completed by hand.

Sketch (*Art*). A preliminary study or design.

Skew. Oblique; at an angle; twisted to one side.

Skew Arch. *See* ARCH.

Skew Back (*Build.*) The bed of an arch, at the springing.

Skew Bevel Wheels (*Eng.*) Bevel wheels whose axes do not intersect.

Skewers (*Foundry*). Wires used to support loose parts of a pattern which have to be detached when the pattern is withdrawn from the mould; the skewers take the place of dowells.

Skidda *or* **Skiddaw Slates** (*Geol.*) A series of ancient marine argillaceous sediments, now somewhat roughly cleaved, which are typically developed on Skidda, near Keswick, in the Lake District. They were originally shales (*q.v.*) with some flagstone and grit, and here and there some thin bands of submarine volcanic tuff. But they have since undergone a considerable amount of disturbance, and have locally been much metamorphosed by the action of bosses of granite which have risen through them, chiefly in Devonian times. Their original extent is unknown, but it must have been considerable, as they form most of the Isle of Man, and must extend from there at least as far as Eastern Westmorland. They may underlie a large area in the south of Scotland, and it is possible that they may extend far towards the borders of Wales. Their exact thickness is not known, but the aggregate thickness visible cannot well be much less than 5,000 ft. The highest beds of the Skidda Slate known for certain occur near Milburn, where they yield graptolites and other fossils of Lower Llandeilo types. Near Keswick other graptolites have been found, which prove that the part of the Skidda Slates occurring near there are of Arenig age. Below these horizons occurs an unknown thickness of older parts of the Skidda Slates, part of which must be of Tremadoc age, and the remainder may be of the same age as the Lingula Flags of Wales. As clements in the scenery of the Lake District the Skidda Slates take an important part, as they form such mountains as Skidda and Saddleback; but, as a rule, they weather into much smoother surfaces than the volcanic rocks which overlie them to the south; and the contrast where the two rocks occur side by side is very striking. The Skidda Slates rarely afford slates which are of much economic importance, though they are employed to a considerable extent as rough building material. Some of the Skidda Slate which has been indurated and partly recrystallised by the intrusion of granite masses—as, for example, the one

to the north of Threlkeld—gives forth a clear sonorous ring when struck, and has often been used for a rude kind of harmonicon. The "musical stones" well known to visitors to the Lake District are of this nature. Some of the more arenaceous bands which occur close to the granite bosses have been thermo-metamorphosed into hornfels; while a few of the argillaceous bands have been dynamo-metamorphosed into true phyllites. The Skidda Slates are succeeded southward of Keswick by a thick pile of andesitic tuffs, highly cleaved, and largely used for slates. These are the well-known "Green Slates." Some bands of andesitic and other lavas occur with them. The whole pile seems to lie unconformably upon the Skidda Slates. It is these rocks which form most of the picturesque scenery of the Lake District, from Ambleside to near Keswick Their position in the geological scale is not certain, and there is nothing to show that they are not of Devonian age. J. G. G.

Skidding. The slipping of a wheel, as distinguished from rolling.

Skimmer (*Foundry, etc.*) An implement used to prevent the scum on the surface of molten metal from entering the mould while the metal is being run in from a ladle.

Skimming Gate *or* **Chamber** (*Foundry*). A cavity. circular in plan, forming an enlargement of the gate (*q.v.*) through which metal enters a mould. The metal flows into the cavity by an opening on one side, and a rotating motion is set up, which carries the pure metal towards the circumference, and the lighter dross and scoriæ towards the centre of the chamber. The iron escapes by means of a gate, and runs straight into the mould. Castings made in this manner are said to be "run with a skimming gate" or "run with a ball."

Skin (*Eng.*) The hard outer layer of a casting, etc., owing to the cooling of the surface having occurred more rapidly than that of the interior. In castings the skin is also apt to contain siliceous matter derived from the mould.

—— (*Zool.*) (1) *See* EPIDERMIS *and* CUTICLE. (2) The name generally given to the pelt of a small animal, the term "hide" being applied to the skin of a large animal.

Skin Effect (*Elect.*) The tendency of any current which is varying in amount to flow in the outer layers of a conductor. On the application of an electromotive force to a conductor, the current will diffuse inwards in a manner similar to that in which heat would diffuse if the surface of the metal were heated. The effect is negligible in small conductors unless the frequency, or the rate of variation in the value of the current, is very great.

Skip. A bucket or similar receptacle for holding loose material which is hoisted by cranes. A basket or box used for raising material from mines.

Skip Pass (*Textiles*). *See* ENTERING.

Skippet (*Archæol.*) A round box in which one of the large seals formerly attached to documents was enclosed for protection.

Skiver (*Leather Manufac.*) The thin grain split of the sheepskin, used for thin bindings, purse leather, and for pocket books. *See* SHEEP *and* CHAMOIS LEATHER.

Skraup's Reaction *or* **Synthesis.** *See* QUINOLINE.

Sky Glow (*Meteorol.*) Accompanies the rising and setting sun, and is due to the diffraction and reflection of light by the minute dust particles in the atmosphere. Sometimes extraordinarily brilliant after volcanic eruptions, as in 1883 and 1902.

Slab (*Build., etc.*) (1) The outside piece of a log when sawn into boards or planks; it is rough on one side. (2) A thin, flat, regularly shaped piece of material, *e.g.* marble.

Slabbing (*Carp.*) Cutting off the rough sides of a balk of timber.

Slack. Small coal used in forges, certain kinds of furnaces, and as a source of carbon in various metallurgical operations.

Slacking Down (*Eng.*) DAMPING DOWN (*q.v.*)

Slack Side (*Eng.*) The loose side of a belt, *i.e.* the portion running away from the pulley which is transmitting the power.

Slag (*Met.*) The masses of fused and often vitreous or glassy silicates, resulting from a great number of metallurgical operations. They contain the major part of the non-metallic materials of the ores, combined with others derived from the fluxes employed, and a certain residuum of the original metal or other constituent. Slags have a number of uses, *e.g.* as BALLAST, HARD CORE, etc. Certain kinds can be made into bricks, others supply a very fair HYDRAULIC CEMENT (*q.v.*) Blast furnace slag supplies SLAG WOOL or SILICATE WOOL (*q.v.*), and basic slag from the Bessemer process is a valuable phosphatic manure. Other slags rich in oxides are useful in smelting operations. *See* COPPER.

Slagging (*Met.*) The withdrawal of the slag from a furnace.

Slag Wool. Sometimes called SILICATE COTTON. It consists of very thin filaments of blast furnace slag. It is used as a non-conducting covering and as an abrasive. By blowing a jet of steam into a stream of molten slag a shower of slag pellets is formed, which in their flight spin out fine threads or filaments of slag. A current of air sucks away the finest portions in the form of slag wool, leaving the pellets and other coarser particles. The wool is further graded according to its fineness.

Slaked Lime (*Build.*) Quicklime to which water has been added. *See also* CALCIUM COMPOUNDS.

Slake Trough (*Eng.*) A trough used in the forge to contain cold water for damping the fire, cooling hot iron, etc.

Slancio, Con (*Music*). With impetuosity.

Slargando (*Music*). Enlarging in tone and decreasing in speed.

Slash (*Cost*). One of a series of narrow slits or openings made in fashionable outer garments for the purpose of showing an under germent, or the openings were filled in with fancy material termed slashings. Slashed costumes were much in vogue during the Tudor period.

Slasher (*Cotton Manufac.*) The Slasher sizing machine. The term is applied also to the attendant. *See* SLASHER SIZING.

Slasher Sizing *or* **Taping** (*Cotton Manufac.*) A popular and economical method of preparing grey cotton warps for the loom. The yarn from the back beams is passed through a size mixture, and after drying is run on to a weaver's beam at the front of the machine. There are several makes: (1) Drum cylinder. (2) Cavity cylinder. (3) Hot air chamber. (4) Steam chests.

Slate (*Geol.*) A term frequently applied to any rock that will split into slabs thin enough to be used for roofing purposes. Geologists, however, restrict the use of the term to rocks which split along planes of cleavage. In Cumberland some of the best slates are cleaved volcanic tuffs; but slates, as a rule, are argillaceous rocks. *See also* SKIDDAW SLATES.

Slates, Roofing (*Build.*) Roofing slates are sorted and sold in various sizes, as follows:—

Doubles . . .	13 in. × 6 in.
Ladies	16 in. × 8 in.
Viscountesses . .	18 in. × 9 in.
Countesses . . .	20 in. × 10 in.
Duchesses . . .	24 in. × 12 in.
Princesses . . .	24 in. × 14 in.
Imperials . . .	30 in. × 24 in.
Queens	36 in. × 24 in.

The sizes most in use are the Duchess and Countess.

Slating Battens (*Build.*) Wood fillets nailed to the common rafters; the slates or tiles forming the roof are fixed to the battens.

Slaughterhouses. *See* ABATTOIRS.

Slay. *See* SLEY.

Sleaker. *See* SLEEKERS.

Sledge *or* **Sledge Hammer** (*Eng., etc.*) A heavy hammer swung by both hands. *See* HAMMERS.

Sleekers *or* **Smoothers** (*Foundry*). Tools used by moulders for smoothing or SLEEKING the interior of a mould after the pattern has been withdrawn. They are made in various shapes to suit different varieties of work.

Sleeking *or* **Smoothing** (*Foundry*). The smoothing of a mould. *See* SLEEKERS.

Sleepers (*Civil Eng.*) Supports laid on the ground or on ballast (*q.v.*) to carry the lines for a railway. They are usually of fir, soaked in creosote; but in countries where wood is destroyed by ants, etc., iron sleepers are used. *See* RAILWAYS.

Sleeper Wall (*Build.*) A dwarf wall to give intermediate support to ground floor joists.

Sleet (*Meteorol.*) Rain mixed with snow or hail. Formed from snowflakes falling through a stratum at a temperature of 32° F. or higher. Falls chiefly in winter and spring.

Sleeve (*Eng.*) A general name for a fitting in the form of a hollow cylinder or tube. Used in a variety of machinery.

Sleeve Piece (*Plumb., etc.*) *See* BRASS THIMBLE.

Sleeve Screw (*Eng.*) A screw cut on the surface of a hollow shaft or sleeve.

Sleeve Wheel (*Eng.*) A wheel whose hub or boss is in the form of a sleeve or hollow cylinder.

Slentando (*Music*). Gradually slackening the speed.

Slewing (*Eng.*) Turning round through an angle. Applied usually to pieces of mechanism such as a crane.

Slewing Gear (*Eng.*) The mechanism by which a crane is turned or slewed about a vertical axis in order to pick up or deposit goods in various positions.

Sley *or* **Slay** (*Lace Manufac.*) A band or strip either of metal drilled with the requisite number of holes or wire woven into a network similar to canvas. Its use is to enable the threads that will eventually compose the lace to be arranged in an orderly and systematic manner, and to keep them apart in the interspace between leaving the warp or beams and entering the guide bars by which the threads are acted upon.

Sley *or* **Slay** (*Weaving*). The going part of a loom, constructed of wood. It carries the shuttle boxes, reed, and trashboard or shuttle race, and assists in beating up the weft. (*See* REED.) The shuttle boxes are fixed at each end of the sley, with the reed between, the body of the sley being bolted to vertical iron supports or sley swords working on a centre stud or shaft. An eccentric motion is imparted to the sley by means of a connecting rod working from the loom crank, whereby more time is allowed for its backward movement (when the shuttle passes through the shed) than for its forward movement (when it beats up the weft). Also termed LAY, LATHE, BATTEN (*q.v.*) *See also* LOOM for illustration.

Sleying (*Weaving*). The operation of drawing the warp threads (after they have been passed through the healds or harness eyes) through the dents or splits of the reed, preparatory to fixing the reed in the sley or batten of the loom for the final operation of weaving. *See* LOOM *and* SET.

Sley Sword (*Weaving*). *See* SLEY.

Slice (*Eng.*) A stoker's tool with a thin blade, used for breaking up a caked fire or clinkers.

—— (*Print.*) The name for (*a*) a flat bladed knife used for lifting ink from the can to the ductor or ink slab. (*b*) The false bottom of a galley made to slide out.

Slickensides (*Geol.*) Pairs of striated surfaces produced on hard rocks by grinding against each other when the rocks have been undergoing disturbance. They very commonly accompany faults (*q.v.*) Slickensides somewhat resemble glacial markings; but in the former the striæ generally terminate abruptly, and minor roughnesses are always present, in which respect they differ sensibly from the smooth furrows and ridges produced by glacial action.

Slicker (*Leather Manufac.*) A tool used in leather manufacture for setting out smoothly and stretching leather.

—— (*Moulding*). A SLEEKER (*q.v.*)

Slide (*Eng.*) A general term for a piece of mechanism which possesses a fully controlled rectilinear motion.

—— (*Music*). (1) An ornament. *See* ORNAMENTS. (2) Part of the mechanism of trumpets and trombones which enables the tube to be lengthened. *See* TROMBONE, *p.* 437. (3) Part of the mechanism of the organ, also called slider. *See p.* 439.

Slide Bars (*Eng.*) The bars which cause the crosshead on the end of a piston rod to move in a straight line. *See* STEAM ENGINE.

Slide Blocks (*Eng.*) The blocks on the ends of the crosshead of an engine, which move or slide along the slide bars.

Slide Lathe (*Eng.*) A lathe with a SLIDE REST (*q.v.*)

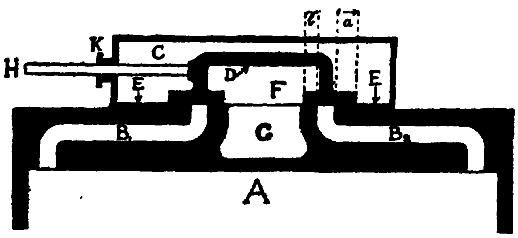
Slide Rest (*Eng.*) A device which holds and also controls the direction of motion of a turning tool. In self-acting lathes it consists of a base or SADDLE sliding on the lathe bed, and moved either by the leading screw or by the back shaft, so as to travel at a definite rate along the bed. Above the saddle is fixed a CROSS SLIDE, above which is the

TOOL HOLDER. The latter can be caused to move in a direction at right angles to the bed of the lathe by means of a screw in the cross slide. This screw is either turned by hand or can be actuated by mechanism from the back shaft. In other lathes the saddle has no self-acting motion, but is fixed to the bed in any required position by a bolt, in the same manner as the back poppet, and carries two slides, one giving a motion parallel to the bed, the other at right angles. In many cases the lower of these slides can be turned round through an angle, so that the tool moves in a direction making an angle with the axis of the lathe, enabling a conical or tapering object to be turned. *See* LATHE.

Slide Rest Lathe (*Eng.*) A lathe with a SLIDE REST (*q.v.*)

Slide Rule (*Eng., etc.*) A very simple and efficient calculator, capable of performing multiplication, division, evolution, and involution of numbers. It consists essentially of two similar scales having graduations proportional to the logarithms of successive numbers, usually from 0 to 100. It can be successfully used by any one without knowledge of logarithms, and its use effects an immense saving of time in engineering and other calculations. The small size, 10 in. long, gives results which are correct to about 1 part in 500; but elaborate instruments, *e.g.* Fuller's Special Slide Rule, give results correct to 1 in 10,000. As a general rule, however, it is most convenient to use tables of logarithms when accuracy greater than that attainable by the 10 in. rule is required.

Slide Valve (*Eng.*) In most forms of the steam engine the admission of the steam to the cylinder is controlled by a valve which is moved backward and forward by the valve gear, over the openings or PORTS leading into the cylinder. A typical form is



shown in the diagram. A is the cylinder; B_1, B_2 are the STEAM PORTS or passages through which steam enters from a VALVE CHEST C, to which it is led from the boiler. Over these ports the valve D slides along a plane surface or SEAT E. The hollow space F within the valve communicates with an opening G, termed the EXHAUST PORT, from which a pipe, termed the EXHAUST PIPE, leads to the condenser, or in the case of a non-condensing engine, to the open air. The valve is moved by the VALVE ROD H, passing through a steam-tight STUFFING BOX K. If the valve be moved to the right the port B_1 is uncovered and steam can enter the left-hand end of the cylinder, driving the piston to the right. The valve then commences to return towards the left, and covers B_1 again, thus cutting off the steam, which commences its expansion in the cylinder. At the end of the stroke the valve has moved so far to the left that B_1 is in communication with the space F, and the steam now escapes through the exhaust port G. The same processes occur (in reversed order) at the other end of the cylinder. It will be seen that the edges of the valve project beyond the ports; this projection is termed the LAP. The distance *a* which the valve projects beyond the steam port when in its middle position is termed the OUTSIDE LAP, and the distance *b* the INSIDE LAP. The effect of the former is to close the steam ports before the end of a stroke, thus rendering expansive working possible; the latter prevents the escape of steam until the valve has moved from the middle position through a distance equal to the amount of the inside lap. If the valve had no lap, steam could enter one of the steam ports whenever the valve was displaced rom the middle position, and would continue to enter until the valve returned to this position, *i.e.* during the whole of each stroke. There would then be no expansion of the steam, and the indicator diagram (*q.v.*) would be approximately a rectangle. The eccentric (*q.v.*) would be so adjusted that its radius—that is, the line joining the centre of the eccentric sheave to the centre of the crank shaft—was at right angles to the crank shaft. The existence of the outside lap requires the eccentric radius to be set in advance of this position, in order to open the valve at the beginning of a stroke; a further small advance is also made in order to open the valve just before the stroke begins. The amount which the valve is actually open at the commencement of a stroke is termed the LEAD. The angle between the crank and the eccentric radius thus exceeds a right angle by an amount termed the ANGULAR ADVANCE, which depends on the lap and lead. The correct adjustment of the positions of the valve and eccentric is termed SETTING the valve.

Slide Valve Spindle (*Eng.*) The VALVE ROD. *See* SLIDE VALVE.

Slide Wire (*Elect.*) The straight wire which furnishes the two variable resistances in a Wheatstone Bridge (*q.v.*) of the straight form known as a Slide Wire Bridge.

Sliding (*Eng.*) (1) In general, any smooth linear motion. (2) In particular, the movement of a tool parallel to the bed of a lathe by means of the SLIDE REST (*q.v.*)

Sliding Blocks (*Eng.*) SLIDE BLOCKS (*q.v.*)

Sliding Fit (*Eng.*) Two parts which fit together easily, yet without the least amount of shake or play, are said to make a sliding fit.

Sliding Friction. The friction (*q.v.*) between two surfaces which are in motion over or relatively to each other.

Slimes (*Met.*) Finely crushed residues from the milling and crushing of ores. *See also* AMALGAMATION PROCESSES *and* METALLURGY.

Sling (*Eng.*) A general term applied to various devices by which an object is suspended, *e.g.* a suitably bent bar or a loop, by which a heavy weight is attached to a crane.

Slip (*Build.*) A thin liquid, or, more correctly, some solid suspended in a liquid, *e.g.* a mixture of clay and water.

—— (*Civil Eng.*) (1) An inclined plane upon which a vessel is supported while being built, or upon which a vessel is placed for repairs. A contrivance for hauling vessels out of the water for repairs. (2) Falling in of the sides of a cutting or embankment is prevented by attention to three points: (*a*) Keeping the slope at a sufficiently low angle; (*b*) Efficient drainage; (*c*) Protection of the surface from weather, chiefly by encouraging the growth of grass and other vegetation.

Slip (*Eng., etc.*) (1) Relative motion of two objects. (2) A thin oil stone for giving a finish to the edge of cutting tools.

—— (*Geol. and Mining*). A miners' term for the displacement accompanying a fault (*q.v.*): also for the amount of that displacement.

—— (*Pot.*) Clay containing so much water that it is of about the consistency of thick cream.

Slip Dock (*Civil Eng.*) A dock which can be emptied and which contains a slip (*q.v.*)

Slip in Motors, etc. (*Elect. Eng.*) The ratio of the frequencies of rotor and stator currents. If ω is the angular velocity of the rotating field, and ω_1 that of the rotor, then the Slip $= \frac{\omega - \omega_1}{\omega}$.

Slip Kiln (*Pot.*) A shallow tank under which are flues. It is used for the conversion of slip into clay by evaporation.

Slip of a Screw Propeller (*Eng.*) The difference between the actual velocity of a steamship and that which it would have if the screw were turning in a fixed nut which exactly fitted the blades. The slip is obviously due to the yielding nature of the water.

Slipper *or* **Slipper Block** (*Eng.*) A SLIDE BLOCK (*q.v.*)

Slipper Brake (*Eng.*) A brake for vehicles running on rails. It consists of blocks attached to the frame of the vehicle in such a way that they can be thrust down on the rails, thus checking the motion.

Slippery Iron (*Met.*) Cast iron containing 2 or 3 per cent. of manganese; so called because it is capable of acquiring a very smooth surface, suitable where there is much friction, as in the cylinders of engines, etc.

Slip Proof (*Typog.*) A proof pulled when the type or matter is on the galley, *i.e.* before it is made up into pages.

Slips (*Bind.*) The ends of the bands or cords to which a book is sewn. They eventually serve to attach the book to the millboards, into which they are laced and then hammered. *See* BANDS, BOARDS, BOOKBINDING, *and* LACING IN.

Slip Winding (*Lace Manufac.*) The operation of winding cotton or other material from skeins or hanks on to wood or similar bobbins.

Slip Winding Engine (*Lace Manufac.*) A machine for accomplishing the foregoing operation.

Slit (*Met.*) The technical term for the nail rods used by nail makers, because they are made by passing bars through a slitting mill (*q.v.*) which slits them up into rods.

—— (*Phys.*) A narrow opening used in spectroscopes and other pieces of apparatus in order to obtain a narrow beam of light. The slit is usually formed in a diaphragm furnished with a device by which the width of the opening can be adjusted.

Slitless Spectroscope (*Astron.*) When a spectroscope is used without a collimator, that is, when parallel light rays are under investigation, the instrument is termed a slitless spectroscope. Another name is an objective prism spectroscope, or, when used for photography, a prismatic camera.

Slitting File (*Eng.*) A file with a thin blade like a knife, used in filing a thin groove.

Slitting Mill (*Met.*) A pair of rolls fitted with steel collars or discs which intermesh and act on the bar iron, as it is fed between the rolls, like a rotary shearing machine.

Sliver (*Textile Manufac.*) A collection of cotton, flax, or woollen fibres which have been formed into a tape-like strand for the purpose of being subsequently spun into yarn. *See* ROVE, SLUBBING *and* LINEN MANUFACTURE.

Slop Closets (*Sanitation*). Closets which are flushed by means of the slops or refuse liquids of the household, instead of by clean water. There are two kinds, *viz.* those in which the waste water runs directly into the basin and those in which, in order to obtain a better flush, the waste water is collected in a siphon, cistern, or tipper, and then discharged in a sudden flush; these latter are known as "automatic slop closets." A number of these closets can be placed on one drain, a single trap, placed at the bottom of the manhole, serving for the whole—a ventilation shaft being provided at the upper end. Slop closets are now placed in many working class houses in the Midlands.

Slope Tile. A glazed earthenware receptacle in which draughtsmen's colours are mixed ready for use. It contains a number of shallow pits with sloping bottoms.

Slop Sink (*Sanitation*). Usually a large "short-hopper" china basin with a siphon trap below, furnished with a grid to prevent obstruction in the pipes. The trap should be connected with the soil pipe, the basin provided with a flushing rim, and flushed from a water waste preventer. A slop sink should only be used when it is undesirable to discharge slops from bedrooms or hospital wards through the water closet.

Slot (*Eng.*) (1) A general term for a long narrow recess or aperture, particularly one in which a pin or block fits. (2) A continuous narrow opening between the rails of a cable-tramway, by which the grip on the car effects connection with the travelling cable.

Slot Drilling (*Eng.*) Cutting a slot by means of a kind of revolving drill. The drill has no vertical motion, the feed being entirely due to the motion of the piece of metal, which is moved along by a table.

Slot Link (*Eng.*) The slotted link used in the LINK MOTION (*q.v.*)

Slotted Armature (*Elect. Eng.*) An armature in which the conductors lie in slots or grooves instead of on the outer surface.

Slotting (*Eng.*) Cutting a SLOT (*q.v.*)

Slotting Machine (*Eng.*) A modification of a shaping machine (*q.v.*), in which the tool moves in a vertical line. It is used for cutting Key ways (*q.v.*) and in various other operations.

Slotting Tools (*Eng.*) The tools used in the SLOTTING MACHINE (*q.v.*) They resemble those used in metal-turning lathes, so far as the form of the cutting edge is concerned; but they are often bent to enable the tool to reach the work, as they move along a straight line which is the direct prolongation of their own axis.

Slubbing (*Cotton Spinning, etc.*) The process in spinning in which the strand or sliver (*q.v.*) is not only further drawn out to a smaller diameter, but also first receives a slight twist as it is wound on to a bobbin by means of a "flyer" affixed to a spindle. The resultant drawn and partially twisted sliver is also termed a Slubbing. *Cf.* ROVE, ROVING.

Slubs (*Cotton Spinning*). Thick places in cotton yarns caused by faulty preparation in the spinning processes.

Sludge (*Eng., etc.*) The muddy sediment deposited in a boiler.

—— (*Sanitation*). The solid and semi-solid portions of sewage, separated from the liquid portions by settling or precipitation.

Sludge Cock (*Eng.*) A wide tap at the bottom of a boiler through which much of the sediment can be washed out by a brisk supply of water from a hose.

Sluice (*Civil Eng., Mining, etc.*) (1) A channel constructed for the purpose of conveying water in a given direction; the water so conveyed. *Cf.* FLUME. (2) A sliding gate or other contrivance in a lock gate or dock gate for effecting or controlling the passage of water. (3) In mining, a trough with an arrangement at the bottom for holding quicksilver, in order to separate the gold from the placer dirt when carried through by a current of water.

Slur (*Music*). A curved line placed over or under two or more notes of different pitch to show that they are to be performed *legato* (*q.v.*) The slur plays an important part in phrasing, and indicates that the first note under the slur is to be accented, and the last note unaccented and played *staccato* (*q.v.*), *e.g.*

DUSSEK.

As will be seen from the next example, the slur often removes the usual position of the accent:

DUSSEK.

An exception to this rule is when two notes in slow time or two long notes are slurred, also when groups of three, four, or more notes are slurred together, in which case the slur signifies simply *legato*; should the slur, however, extend to the accented notes, as in the following example, the above rule holds good:

WEBER.

In vocal music the slur indicates that those notes "slurred" are to be sung to one syllable. In stringed instrument music the slurred notes are played by one stroke of the bow. *See also* STACCATO *and* TIE.

—— (*Print.*) When from any cause during the actual process of printing the impression is smeared, it is said to slur.

Slype (*Architect.*) A mediæval name for a narrow passage between two buildings.

Sm (*Chem.*) The symbol for SAMARIUM (*q.v.*)

Small Capitals (*Typog.*) Of a smaller size than the regular capitals of a fount. They are used for running titles, chapter headings, side headings, and for emphasising certain phrases, proper names, etc.

Small Circle (*Geom.*) The circle formed by the intersection of the surface of a sphere with any plane cutting it, but not passing through the centre. *See* SPHERE.

Small Octave (*Music*). The octave between tenor C and middle C. *See* PITCH.

Small Pica (*Typog.*) Type between Pica and Long Primer in size. *See* TYPES.

Small Post (*Paper.*) A sheet of writing paper measuring 19 × 15½ in.

Smalt. *See* COBALT COMPOUNDS.

Smaltine (*Min.*) Cobalt diarsenide, $CoAs_2$; composition variable as a passage to Cloanthite (nickel diarsenide) is observed. Cubic, in brilliant tin white crystals; also massive. It is usually associated with other ores of cobalt and with ores of copper, silver, nickel, and arsenic. From Cornwall, Force Crag in Cumberland, Argyllshire, and Stirlingshire. More abundantly abroad at Freiberg, Schneeberg, and Annaberg in Saxony, in Bohemia, Tunaberg in Sweden, Chili, Missouri, etc.

Smalto (*Dec.*) Roman mosaic work, composed of very small squares of coloured glass.

Smelting (*Met.*) The separation of metals from their ores by the combined agency of heat and chemical action. The process usually requires the addition of FLUXES (*q.v.*), and oxidising or reducing agents which may consist entirely of gases formed in, or introduced into, the furnace. *Cf.* MELTING. *See also* METALLURGY.

Smith (*Eng.*) A general term for a mechanic who forges metals with a hammer, but often distinctively applied to a blacksmith, *i.e.* one who produces wrought-iron work, as distinguished from a coppersmith, tinsmith, and whitesmith.

Smith's Shop *or* **Smithy.** A forge; a workshop provided with hearths and anvils, etc., and in a large shop with power hammers, cranes, and other machinery.

Smithsonite (*Min.*) In Britain this term is sometimes used for HEMIMORPHITE (*q.v.*); but it has been used in America for the Carbonate of Zinc, CALAMINE.

Smoke. The gaseous products of combustion mixed with other gases given off by fuel, together with a great number of fine particles of unburnt carbon. Smoke thus consists largely of fuel which is being wasted.

Smoke Box (*Eng.*) A chamber in a locomotive or other fire-tube boiler at the end of the tubes or flues opposite to the fire-box. The products of combustion collect in the smoke-box in their passage to the smoke-stack. *See* BOILERS.

Smokeless Coal (*Eng.*) Anthracite and similar varieties of coal. *See* COAL.

Smooth Cut File (*Eng.*) One with a considerable number (*e.g.* 70) of teeth to the inch.

Smoother (*Foundry*). *See* SLEEKER.

Smoothing Plane (*Carp. and Join.*) This tool is used for smoothing the surface of wood after the jack and trying plane have been used. *See also* PLANES.

Smorzando, Smorzato (*Music*). Smothering the tone; equivalent to morendo.

Smudge (*Plumb.*) A mixture of lampblack, chalk, etc., used to prevent solder from adhering to lead where not required.

Sn (*Chem.*) The symbol for TIN (*q.v.*)

Snap (*Eng.*) The cup-shaped tool used for closing or forming the head of a rivet. The tool is held over the head of the redhot rivet and struck with a hammer.

Snap Head Rivet (*Eng.*) A rivet with a cup-shaped head, formed by a snap.

Snarls (*Cotton Spinning, etc.*) Twisted loops or kinks which appear at intervals on a thread; caused mainly by uneven tensioning or bad setting of the faller mechanism and carriage of a mule.

Sneck (*Build.*) A local term for a latch or door fastening.

Snecked Rubble (*Build.*) Masonry formed of rough irregular stones, but arranged in such a manner as to secure an effective bond.

Snell's Law (*Light*). When a ray undergoes refraction (*q.v.*) in passing from one medium to another, there is a ratio between the sine of the angle of incidence and the sine of the angle of refraction which is constant for any pair of media, or

$$\frac{Sin\ i}{Sin\ r} = \mu.$$

See also REFRACTION *and* INDEX OF REFRACTION.

Snifting Valve (*Eng.*) A valve used to allow the escape of gases, water, etc., from an enclosure when the pressure exceeds a certain amount; also called a BLOW VALVE or TAIL VALVE.

Snips. Shears for cutting zinc, tinplate, etc.

Snow (*Meteorol.*) Snow consists of the aqueous vapour of the atmosphere precipitated in the form of light, loosely packed masses of ice crystals. It may be said that one foot of snow represents roughly about one inch of rain.

Snow Guards (*Build.*) Iron rails, etc., fixed at the eaves of a roof to prevent the sudden fall of large masses of snow from the roof.

Snow Line (*Meteorol.*) A line that marks the height below which all the snow that falls annually melts during the summer. Above this line lies the region of perpetual snow.

Soakers (*Plumb.*) Pieces of lead or zinc fixed in the angle at the junction of a wall and the slates on a roof in order to prevent the rain running down the wall inside the roof.

Soaking (*Met.*) Allowing a freshly cast ingot of steel to remain in a SOAKING PIT (*q.v.*) in order that its temperature may become uniform throughout, prior to rolling. If allowed to cool in the air the outside cools much more rapidly than the interior, which may remain in a fluid condition for some time.

Soaking Pits (*Met.*) A bed of brickwork moulds in which the freshly cast *steel* ingots are placed as soon as stripped. When once heated, the pits are kept hot by the fresh ingots. They are usually built below the floor of the rolling mill, and kept covered to exclude air.

Soap. In popular language this is a substance soluble in water and possessed of lathering and detergent properties. These qualities are practically restricted to the soaps of alkali metals. A soap is a salt of which the basic radicle is a metallic oxide, while the acid radicle is derived from a fatty acid. Fats, such as tallow or linseed oil, are compounds in which the radicle of an acid replaces hydrogen in glycerine. The acids concerned are therefore called fatty acids, and in the making of a soap from a fat the glycerine is formed and set free. Many of the soaps are, however, far from conforming to the popular conception of a soap. The term "soap" is practically confined to the potash and soda salts of the highest members of the fatty acid series, especially palmitic acid and stearic acid. With potash we get soft soaps, with soda hard soaps, and intermediate varieties by the use of both alkalies. The soaps of the heavy metals are insoluble; and although they have their uses, they refuse to wash anything. The manufacture of soap is of considerable antiquity, but cannot be traced back much before the beginning of the Christian era. Pliny describes a product from goat tallow and wood ashes, and Pompeii possessed a soap factory. Of the chemistry of soap nothing was known before the time of Chevreul. The PROCESSES OF SOAP MAKING fall under two great heads. In one set the fat itself is treated with the alkali direct; in the other the fatty acid is first prepared from the fat and then treated with the alkali after the separation of the glycerine also formed. The former principle was the only one used until comparatively recently; but the latter is fast gaining ground, and seems likely to supplant its older rival altogether. One great reason of this is, that when the new methods are adopted it is far cheaper and easier to extract the glycerine (which has a higher price than most soaps) than is the case when the fat is saponified direct. The indirect saponification methods, if the term may be allowed, are again subdivisible into two. In one the fatty acid is produced by chemical means, and in the other the production of acid and glycerine is the result of the action of an enzyme from a seed, especially from the seeds of the castor oil plant and those of the wild liquorice (*Abrus precatorius*). Taking the older method of direct saponification first, we find that to make a hard soap the fat is boiled with a caustic soda lye until the whole of the fatty acid has been converted into the alkaline salt. The quantity required for a given weight of the fat (or, more usually, mixture of different fats) is roughly known, and gradient tests exist by which the progress of the saponification may be estimated. When saponification is complete the soap is in a state of solution in the water present, and must be precipitated. This process is called RELARGING, and is done by throwing in dry common salt. This dissolves in the water, and forms a solution in which the soap is insoluble. It therefore rises to the top in the solid form, and the sub-lye, containing the salt and glycerine, is run out from beneath it. Before relarging, the soap maker judges by the taste or "touch" whether the soap contains too large an excess of alkali or too large an excess of fat, adding more of one or the other as may be required. When the sub-lye has been drawn off, the soap is finished or clear boiled by boiling with lye too strong to dissolve it. This purifies it, and the sub-lye having been again run off, the soap is ladled into the frames, where it sets. In some cases in making high priced soaps, a "cleansing boil," or even two, is given after finishing. This is done with strong salt water, and its object is to free the soap from dirt and any excess of alkali. A soft soap is much simpler to make, as no relarging is required. The above description is an outline of a typical process, but the details vary almost indefinitely, according to the fat used and the purpose for which the soap is intended. Soaps are, of course, MEDICATED, SCENTED, and DYED in many ways. In the best soaps the drug or scent is added by milling, *i.e.* cutting the soap into thin shavings, which are then wetted with the liquid to be incorporated and again made into cakes or bars by being pressed through a moulder. A majority of the soaps upon the market are "filled." FILLINGS: Soap has the power of incorporating with and holding

large quantities of foreign matter. Rosin, common salt, potassium chloride, potassium and sodium sulphates, farina and water glass, are all common fillings. They are to be regarded as adulterants pure and simple, as they are cheaper than soap and do not possess its useful properties. It is true that rosin makes salts analogous to soaps with metallic oxides; but these soaps, like lime soap or iron soap, are soaps only from the point of view of chemical classification. Rosin is added during saponification, the other fillings at the final stage before framing or even while the soap is setting in the moulds. The glycerine is sometimes incorporated with a soap—especially in the toilet soaps made by the so-called "cold process," *i.e.* by extra strong lyes at temperatures well below boiling heat—but cannot be called a filling, as it is an essential part of the fat from which the soap is made. In former times, soap boilers made their own caustic alkali from quicklime and the carbonate of the alkali. This practice has been lessening ever since caustic soda could be cheaply bought ready made; but it still prevails to some extent on the Continent, particularly in Russia. When a soap is to be prepared by the INDIRECT CHEMICAL PROCESS, the fatty acid is simply neutralised with the alkali or its carbonate. There is no glycerine, and very little finishing is needed, as the fatty acid is always much freer from foreign matter than the original fat. The fermentation method for producing the fatty acids consists of making a pulp of the seeds of *Ricinus*, or of the plant chosen, and keeping it in the warm fat in the presence of mineral acid. It is claimed for this method that the glycerine obtained pays all the expenses, so that the whole of the money received by the sale of the soap is clear profit. ROSIN SOAP is used, as already stated, as an adulterant of ordinary soaps, but is also employed as a raw material for making other resinates, some of which, such as the resinates of lead and manganese, are used as dryers by varnish makers. If rosin is boiled in solution of carbonate of soda, carbonic acid gas is given off, and a solution of soda combined with resinic acid is left. If, say, nitrate of lead is added to the solution of resinate of soda, resinate of lead is obtained as a precipitate. Other resinates of heavy metals are obtained by similar methods. Rosin soap enters into the composition of some of the waterproofing mixtures. Several patents have been taken out for using the soaps of the heavy metals, such as the oleate, stearate, and palmitate of alumina, in waterproofing. Lead plaster, or oleate of lead, is a well known insoluble soap used in medicine. LIME SOAPS are used in making cheap lubricants, and on the Continent are precipitated from waste baths of ordinary soap for the preparation of illuminating gas. The soaps of alumina, zinc, and magnesium are used to increase the viscosity of heavy machine oils. In candle making, lime soap is largely used, and it is also employed in making fatty acids, the fat being saponified with milk of lime under a pressure of 160 to 180 lb. to the square inch, and the lime soap being afterwards decomposed with dilute sulphuric acid, which forms sulphate of lime and sets free the fatty acid. The acid rises to the surface of the water, and is skimmed off, while the insoluble sulphate of lime forms a sediment at the bottom. With the exception of lime soap and lead plaster, no heavy metal soap is made by direct saponification. LEAD PLASTER is prepared by heating olive oil with litharge and lime soap, as just described. The others are obtained as precipitates by adding a solution of a metallic salt to one of common soap. Many of these insoluble soaps have pronounced colours, and the mottling of soap is occasionally effected by stirring in a little solution of iron, which throws down its equivalent of dark iron soap. Nowadays, however, mottling is done chiefly by stirring ultramarine or black oxide of manganese into the soap in the frames, choosing the time for doing so as late as possible, that the mottling may not accumulate at the bottom. The heavy pigment would rapidly sink if the soap were fluid enough. POLISHING SOAPS are ordinary curd soaps into which some abrasive material, such as ground pumice stone, fuller's earth, prepared chalk, kieselguhr, etc., has been crutched before allowing the paste to cool in the frames. In the same way disinfecting products are also introduced. SOAP POWDER is chiefly ground washing soda (or sometimes ordinary soda ash), mixed with varying percentages of dried soap, as it comes from the frames. DYEING SOAPS are ordinary household soaps to which aniline dyes (with a mordant, if necessary) have been added prior to cooling. So-called superfatted toilet soaps have some emollient, such as lanoline, vasceline, spermaceti, incorporated by remelting or milling. The object is to correct any excess of free alkali, which tends to roughen the skin. The following are a few typical analyses of soaps:—

	Fatty Anhydrides.	Combined Alkali	Free Alkali.	Salt.	Sulphate of Soda.	Water, etc.
Tallow Curd . . .	66·60	7·51	0·50	1·35	0·2	23·84
Bleached Palm . . .	66·20	7·83	0·40	2·0	trace	28·52
Imitation Castile . .	61·45	8·46	1·16	1·17	1·23	26·53
Milled Toilet . . .	83·6	9·8	0·24	—	—	5·36
Primrose	*46·88	7·12	0·14	0·14	0·07	30·25
Olive Marseilles, No. 1	62·66	7·27	0·80	0·76	0·8	32·51
The Transparent Soaps						
Cold process . . .	38·0	5·57	2·22	—	—	55·53†
Spirit process filled with sugar . . .	65·6	7·73	—	—	—	26·67‡
Spirit process without sugar . . .	68·1	7·62	—	—	—	24·28

* Also 15 per cent. of resinous anhydrides.
† 28 per cent sugar. ‡ 14 per cent sugar.

Among soft soaps the following are typical:—

Soap.	Fatty Acids.	Alkali (K_2O).	Water, Salts, Glycerine, etc.
Rape Oil . . .	51·7	10·0	38·3
Olive	48·0	10·0	42·0
London make .	45·0	8·5	46·5

See also SOFT SOAPS, WHITE SOAP, YELLOW SOAP.

Soap Bark (*Botany*). The soap tree of South America (*Quillaia saponaria*; order, *Rosaceæ*) yields the soap or Panama bark used in medicine, and as a cleaning agent for silk and delicate fabrics.

Soap Bubbles (*Phys.*) The walls of a soap bubble are formed by a thin film of soap solution, which tends to contract owing to the surface tension of its two surfaces; this tendency to contract is counteracted by the pressure of the enclosed air or other gas, which is always greater than the pressure of the external air. If p be the difference between the internal and external pressures, T the surface tension of the bubble, and r its radius, then $p = \frac{4T}{r}$.

Soapstone (*Min.*) A massive variety of TALC (*q.v.*) It is used in the East for ornamental carving and turning. Commercially it is used in the manufacture of gas burners, as a dry lubricant, in the manufacture of porcelain, and on account of its absorptive property when in fine division for removing grease from cloth.

Soapsuds (*Eng.*) Used as a lubricant for the cutting tools in working wrought iron and steel.

Soave, Soavemente (*Music*). Sweetly, delicately.

Sock (*Archæol.*) The light low shoe worn by comic actors in Greek and Roman drama; the symbol of comedy. *Cf.* BUSKIN.

Socket (*Carp. and Join.*) The recess or opening into which the pin of a dovetail fits.

—— (*Eng., etc.*) A hollow or cavity into which some object fits, especially the enlarged end of a length of pipe. *See* FAUCET.

Socket Chisel (*Carp.*) A heavy mortising chisel with a tubular metal socket or handle, into which a wooden handle is fixed.

Socle (*Architect.*) A slab-like member, square in plan and less in height than in width, used under a pedestal or vase. A CONTINUED SOCLE is similar to the above, but is continued round a building, instead of being used only under certain members of it.

Soda (*Chem.*) A name loosely used to denote either sodium hydroxide or sodium carbonate. The context alone enables one to tell what is meant. In some analytical reports the word means sodium oxide, Na_2O. The term soda is not used, or only where no ambiguity can arise, by accurate writers on chemistry. *See also* ALKALI *and* SODIUM COMPOUNDS.

Soda Ash (*Chem.*) Dry commercial sodium carbonate. *See* ALKALI.

Soda Bleach. *See* SODIUM PEROXIDE, *under* SODIUM COMPOUNDS.

Soda Crystals (*Chem.*) Crystallised sodium carbonate, $Na_2CO_3 10H_2O$. *See* ALKALI.

Soda Nitre (*Min.*) Nitrate of sodium, $NaNO_3$. Soda = 36·5, nitric acid = 63·5 per cent. Rhombohedral; also in efflorescent forms. White, greyish, or brown. It is used in the manufacture of nitric acid and potassium nitrate. It occurs as a surface deposit on the Pampas of Chili. It is a common associate of Gypsum, Rock Salt, etc.

Soda Waste (*Chem.*) Same as alkali waste. *See* ALKALI; CHANCE'S PROCESS; *and* SODIUM THIOSULPHATE, *under* SODIUM COMPOUNDS.

Sodium (*Chem.*) Na. Atomic weight, 23. A silvery white metal which rapidly becomes coated with oxide on exposure to air. Hence it is kept under hydrocarbon oil in a well-stoppered bottle. On the large scale it is washed with oil and put up in hermetically sealed drums. At ordinary temperatures it is very soft, and can be moulded in a sodium press, but at −20° C. it possesses ordinary metallic hardness, and is malleable and ductile in an atmosphere that cannot oxidise it. It is one of the lightest of metals (sp. gr. = 0·973), and is fusible and volatile (m.p. = 95·6° C., b.p. = 742° C.); specific heat = 0·29 (solid) and 0·24 (liquid). Although generally seen in sticks, sodium can be crystallised in a similar manner to Prismatic Sulphur. Recent investigations show that the molecule of sodium is monatomic. When sodium or any compound containing it is introduced into a colourless Bunsen burner flame a vivid yellow flame is produced, even by extremely small quantities. Sodium is stable in perfectly dry air or oxygen, but it oxidises readily in moist air; reacts very energetically with water, replacing half the hydrogen at the ordinary temperature, and forming sodium hydroxide, $2H_2O + 2Na = 2NaOH + H_2$. It combines directly with sulphur and with the halogens; dissolves in liquefied ammonia, and reacts with gaseous ammonia to make sodamide (*q.v.*) It combines with hydrogen to make the hydride (NaH). Dilute acids have an energetic action on sodium, which is very high on the electro-positive scale; hence if it were practicable to employ it instead of zinc in a voltaic cell, a very high E.M.F. would be obtained. It forms only one important alloy, *viz.* with potassium. The alloy is fluid at ordinary temperature, and has the appearance of mercury; sometimes used in thermometers, as it is fluid up to 440° C. SODIUM AMALGAM is formed by putting clean pieces of metallic sodium very carefully into mercury in a porcelain mortar; much heat is evolved. The amalgam will slowly decompose water, and can be employed to amalgamate iron and platinum. It is also used as a reducing agent in organic chemistry and as a solvent in extracting gold and silver. Sodium occurs native, principally as common salt (sodium chloride), NaCl; also as borax (sodium pyroborate), $Na_4B_2O_7$, and as Chili saltpetre (sodium nitrate), $NaNO_3$. These salts, being soluble, could only be deposited in an almost rainless climate. Other sources of sodium are insoluble, *e.g.* the mineral cryolite, Na_3AlF_6, also the mineral Albite and the sodalite group of silicates. PREPARATION: in Castner's process fused sodium hydroxide is put in a large tank heated to about 330° C. The negative electrode or cathode at which the sodium comes off passes up into the liquid from below, and is surrounded at the top by wire gauze. The metal floats in the molten liquid, and is ladled out at intervals.—H. W. H.

Sodium Compounds. SODIUM MONOXIDE, Na_2O, although theoretically the normal oxide, is not the most important; obtained by heating sodium with the theoretical quantity of sodium nitrate,

$$10Na + 2NaNO_3 = 6Na_2O + N_2.$$

It is a grey, fusible powder, and is soluble in water without evolution of oxygen, $Na_2O + H_2O = 2NaOH$. SODIUM PEROXIDE, Na_2O_2. Sodium in thin pieces is placed on aluminium trays and allowed to travel slowly down iron tubes kept at 300—400° C. Air free from water and carbon dioxide is passed over and oxidises it. Sodium peroxide is a white, friable mass with a faint yellow tinge; not deliquescent when pure. Dropped into cold water it dissolves with scarcely any chemical action; but if cold water be dropped upon it, torrents of oxygen are evolved. This makes a convenient laboratory method for preparing oxygen. Sodium peroxide is decomposed by hot water, $2Na_2O_2 + 2H_2O = 4NaOH + O_2$. On moderate heating it simply darkens in colour. It acts violently on any oxidisable organic substance (*e.g.* it sets paper on fire). It is dangerous to heat it on charcoal or to add concentrated sulphuric acid to it. It sets fire to glacial acetic acid, absorbs carbon dioxide, and evolves oxygen; but the volume of the oxygen is only one-half that of the carbon dioxide, $2Na_2O_2 + 2CO_2 = 2Na_2CO_3 + O_2$. This may be used to prove the formula. Soda-bleach is a solution of this substance in dilute hydrochloric acid, and acts like hydrogen peroxide. SODIUM HYDROXIDE, NaOH (caustic soda): Obtained (1) as described under ALKALI (*q.v.*), (2) by precisely similar methods to

those described for potassium hydroxide. *See* POTASSIUM COMPOUNDS. Sodium hydroxide may be purified for use as a reagent by dissolving in alcohol and filtering, afterwards evaporating to dryness in a silver dish. Solid sodium hydroxide, on exposure to air, forms a viscous liquid by absorbing water, and afterwards becomes coated with carbonate by absorption of carbon dioxide. Soluble in water. with considerable rise of temperature; fuses at 310° C., and in the fused state attacks glass. For uses *see* ALKALI. SODIUM HYDRIDE, NaH (Moissan): Obtained by heating sodium in dry hydrogen to about 370°C.; forms white crystals (sp. gr. ·92), spontaneously inflammable in moist air. It liberates carbon from carbon dioxide; with water it gives caustic soda and hydrogen, $NaH + H_2O = NaHO + H_2$. SODIUM CHLORIDE, NaCl: Found native (impure) as rock salt; also obtainable by evaporating brine. Pure sodium chloride can be obtained from strong brine by leading a current of hydrochloric acid gas through it, thus increasing the concentration of chlorine ions and precipitating small crystals which are washed in strong hydrochloric acid. Pure salt is of a clean white colour, and is slightly deliquescent. It is about equally soluble in cold and hot water. Strong brine boils at 107·5° C. Besides its uses in the preparation of food it is employed in salt-glazing earthenware and in the manufacture of sodium carbonate and sodium hydroxide. SODIUM HYPOCHLORITE, NaClO. *See* HYPOCHLOROUS ACID. SODIUM CHLORATE, $NaClO_3$: Pass chlorine into hot milk of lime, and so form chloride and chlorate of calcium. To the mixture add salt cake (Na_2SO_4) and crystallise out. It is white and deliquescent. Unless mixed with potassium chlorate it is of no use for the preparation of oxygen. Its principal use is as an oxidising agent in organic chemistry. SODIUM FLUORIDE (NaF): Fuse dry sodium carbonate with fluorspar—

$$Na_2CO_3 + CaF_2 = 2NaF + CaO + CO_2.$$

The product is white and soluble. A solution of it is used in softening water for boilers. SODIUM SULPHITE (Na_2SO_3) *and* BISULPHITE ($NaHSO_3$) can be obtained as follows: (1) Saturate a known quantity of sodium hydroxide or carbonate with sulphur dioxide gas (this gives the bisulphite),

$$NaOH + SO_2 = NaHSO_3.$$

(2) Add the same quantity of alkali to the saturated solution (this gives the normal sulphite),

$$NaHSO_3 + NaOH = Na_2SO_3 + H_2O.$$

The bisulphite is the more useful as it contains a higher percentage of the valuable ingredient (SO_2). It is used as a reducing agent, and is employed in photography, bleaching, and as a disinfectant. It forms crystalline derivatives of fixed melting point, with aldehydes and many ketones. SODIUM METABISULPHITE, $Na_2S_2O_5$: Made by passing SO_2 over powdered washing soda, $Na_2CO_3 10H_2O$. It is white, crystalline, and soluble, and smells of sulphur dioxide. Used for the same purposes as the acid sulphite. SODIUM SULPHATE, Na_2SO_4: This substance is obtained most cheaply from the Stassfurt deposits. It can also be obtained by crystallising salt cake from the Leblanc process (alkali manufacture). It is used in glassmaking and in preparing other sodium salts. Its solution in water is a mild aperient (Glauber's Salts). SODIUM THIOSULPHATE (hyposulphite), $Na_2S_2O_3$: Prepare by adding sodium sulphate to calcium thiosulphate (obtained from alkali waste, calcium sulphide, by atmospheric oxidation),

$$Na_2SO_4 + CaS_2O_3 = Na_2S_2O_3 + CaSO_4.$$

Filter from the calcium sulphate and crystallise. The crystals are large and clear. They dissolve in water with fall of temperature; but the solution is not very stable. It is used in photography as "Hypo" to dissolve unaltered silver salts, and in chlorine bleaching as an Antichlor. In analytical chemistry it is employed in conjunction with standard iodine for estimating oxidising or reducing agents, $2Na_2S_2O_3 + I_2 = Na_2S_4O_6 + 2NaI$. SODIUM AMIDE *or* SODAMIDE ($NaNH_2$): Pass dry ammonia gas over heated sodium, $2Na + 2NH_3 = 2NaNH_2 + H_2$. It is a waxy mass of crystalline structure, and is chiefly interesting on account of two reactions: (1) With nitrous oxide (N_2O), on heating, it yields sodium azoimide, NaN_3 (*see* AZOIMIDE).

$$2NaNH_2 + N_2O = NaN_3 + NaOH + NH_3.$$

(2) On heating with carbon it yields sodium cyanide (used in extracting gold), $NaNH_2 + C = NaCN + H_2$. SODIUM NITRITE, $NaNO_2$: Take one part of Chili saltpetre to three of granulated lead. Fuse the saltpetre and add the lead in small quantities. The final product is extracted with pure water—

$$NaNO_3 + Pb = NaNO_2 + PbO.$$

A little caustic soda is also formed, and this tends to dissolve PbO; if this be exactly neutralised with nitric acid, the PbO will be precipitated. A new process consists in reducing sodium nitrate by carbon monoxide in the presence of quicklime—

$$NaNO_3 + CaO + CO = NaNO_2 + CaCO_3.$$

It forms colourless deliquescent prisms, stable on heating. It is used in the preparation of dye stuffs for the diazotisation of amines. If R be an organic radicle,

$$RNH_2 + NaNO_2 + 2HCl = R - N = N - Cl + NaCl + 2H_2O$$

SODIUM NITRATE, $NaNO_3$ (also called Chili saltpetre and cubic nitre): Obtained from beds just below the surface soil in Peru and Chili. Can be recrystallised if required pure. It is slightly deliquescent, which unfits it for many purposes (such as gunpowder making) to which potassium nitrate is applied. It is principally employed for manure and for preparing potassium nitrate and nitric acid, and on strongly heating it yields the nitrite with oxygen. SODIUM ORTHOPHOSPHATES (*see* PHOSPHORIC ACID): (1) *Tri* sodium phosphate, Na_3PO_4. Obtain by adding caustic soda in suitable quantity to a solution of common sodium phosphate and evaporating for crystals, $Na_2HPO_4 + NaOH = Na_3PO_4 + H_2O$. It is strongly alkaline to litmus, and absorbs carbon dioxide, which decomposes it. It is quite stable on heating, either alone or with carbon. It gives quantitatively a yellow precipitate with Silver Nitrate. (2) *Di* sodium phosphate (commonest form), $Na_2HPO_4 12H_2O$. Add sodium carbonate to phosphoric acid till no further effervescence. Filter and crystallise; large crystals, the solution of which gives a slightly alkaline reaction to litmus. On heating alone it yields the pyrophosphate (*q.v.*) When added to silver nitrate the silver is all precipitated, but the phosphate is not, and the liquid becomes acid to litmus.

$$3AgNO_3 + 2Na_2HPO_4 = Ag_3PO_4 + 3NaNO_3 + NaH_2PO_4.$$

(3) *Mono* sodium phosphate (NaH_2PO_4). Formed by passing a rapid current of carbon dioxide into a solution of common sodium phosphate. Large clear crystals with acid reaction. The solution does not completely precipitate silver nitrate. SODIUM AMMONIUM HYDROGEN PHOSPHATE, $NaNH_4HPO_4$ (Microcosmic salt), is a white solid crystallising in monoclinic prisms, which contain 4 molecules of

water; very soluble in water; decomposes on standing in air, forming sodium dihydrogen phosphate; when strongly heated it gives sodium metaphosphate—

$$NaNH_4HPO_4 = NaPO_3 + H_2O + NH_3.$$

On this account it is largely used in blowpipe analysis, as the sodium metaphosphate so produced has the property of dissolving many metallic oxides when melted, and on cooling characteristically coloured beads are obtained. Microcosmic salt occurs in guano: it can be made by mixing solutions of the common sodium and ammonium phosphates and allowing to crystallise, or by adding the requisite amount of ammonium chloride to a hot strong solution of common sodium phosphate, when common salt crystallises out and is removed, and the microcosmic salt crystallises out on cooling—

$$Na_2HPO_4 + NH_4Cl = Na.NH_4.HPO_4 + NaCl.$$

SODIUM PYROPHOSPHATE, $Na_4P_2O_7$: Obtained by heating common sodium phosphate, dissolving in water and crystallising—

$$2Na_2HPO_4 = Na_4P_2O_7 + H_2O.$$

Colourless crystals, alkaline reaction. Yields orthophosphate by boiling with dilute acids. SODIUM METAPHOSPHATE, $NaPO_3$: Easily obtained by fusing microcosmic salt and quickly cooling the clear bead, $NaNH_4HPO_4 = NaPO_3 + NH_3 + H_2O$. A deliquescent solid whose molecular formula is said to be $(NaPO_3)_6$. Coagulates albumen and gives a white precipitate with silver nitrate. SODIUM ORTHOBORATE, Na_3BO_3: Fuse B_2O_3 with caustic soda. Unstable product, $B_2O_3 + 6NaOH = 2Na_3BO_3 + 3H_2O$. SODIUM BIBORATE or Pyroborate, $Na_2B_4O_7$: This is common borax, and can be recrystallised from the native mineral. When heated it intumesces, and afterwards melts down into a clear glassy bead. Two different crystalline forms are known: (1) Octahedral, containing $5H_2O$, crystallising above 56°C. (2) Prismatic, containing $10H_2O$, formed below 56°C. Borax is used in cleaning because, (*a*) with water it yields by hydrolysis a certain number of hydroxyl ions, the detergent properties of which are well known. (*b*) On fusing it dissolves many metallic oxides, which act as films upon metallic surfaces. *See also* BORON COMPOUNDS. SODIUM SILICATES (*see* SILICON COMPOUNDS): An indefinite mixture called WATER GLASS is prepared by fusing finely divided flints with caustic soda under pressure to 200°C., and extracting with boiling water; also by fusing sodium carbonate and sand with a little charcoal till all carbon dioxide is expelled, and extracting with hot water. Colourless or yellow mass, semi-transparent. Decomposed when in solution by any acid, even carbonic. Used in fresco painting, for hardening the surface of stone, and for fireproofing wood. It is frequently added to the cheaper kinds of soap. SODIUM TUNGSTATE, $Na_2WO_4 2H_2O$: Fuse the mineral wolfram with sodium carbonate; extract with water and crystallise. It is used as a mordant in calico printing. SODIUM STANNATE, Na_2SnO_3: Fuse powdered tinstone with caustic soda, dissolve the resulting mass in water, and crystallise—

$$2NaOH + SnO_2 = Na_2SnO_3 + H_2O.$$

It is chiefly used as a mordant for Eosine and other dyes. It undergoes change on exposure to air, being decomposed by carbon dioxide. SODIUM CARBONATE (washing soda), $Na_2CO_3 10H_2O$: Prepared by the Leblanc method or Solvay method. *See* ALKALI. It is white and crystalline, very soluble in water, making an alkaline solution. The crystals undergo aqueous fusion at 50° C., then dry up and fuse at 850° C. (igneous fusion). SODIUM BICARBONATE, $NaHCO_3$: Prepared by the Solvay process. *See* ALKALI. It forms small prismatic crystals, and is less soluble than the normal carbonate. The crystals are decomposed by heat—

$$2NaHCO_3 = Na_2CO_3 + CO_2 + H_2O.$$

The solution is faintly alkaline, and on heating gives off CO_2. When a little of this substance is mixed with flour and water and heated, the weak vegetable acids in the flour cause a gentle evolution of CO_2; thus the substance acts as baking powder. SODIUM SESQUICARBONATE, $Na_3H(CO_3)_2 + 2H_2O$, is found native as Trona, and has been known from early times. SODIUM FORMATE, $NaHCO_2$, or $HCOONa$: Neutralise some caustic soda with formic acid solution. Forms a white deliquescent substance, giving sodium oxalate on heating—

$$2HCOONa = Na_2C_2O_4 + H_2.$$

It is a reducing agent, *e.g.* reduces silver nitrate. SODIUM ACETATE, $NaC_2H_3O_2$, or CH_3COONa: Treat pyroligneous acid, obtained from the distillation of wood, with caustic soda till neutral; evaporate, and heat the residual sodium acetate till it fuses; then recrystallise. It forms transparent and easily soluble prisms. Its principal use is, in analysis, to remove strong acidity from a solution. Suppose a solution contains free HCl (ionised), the addition of sodium acetate replaces this by free acetic acid (almost non-ionised),

$$\overset{+}{H}\,|\,\overset{-}{Cl} + \overset{+}{Na}\,|\,CH_3COO = \overset{+}{Na}\,|\,\overset{-}{Cl} + HCH_3COO.$$

SODIUM PHENATE, NaC_6H_5O, or $NaOC_6H_5$: Formed by dissolving phenol (carbolic acid) in sodium hydrate. It is white, becoming brown on exposure, and is one constituent of "carbolic soaps," being antiseptic and detergent. (For other sodium salts *see under* the particular acid.) H. W. H.

Sod Oils. The oils expressed from skins which in the process of currying have been treated with cod, whale, or olive oils. The French product (Möellon) is obtained from skins used solely for this purpose. When refined, genuine sod oils are valuable for lubricating watches and similar delicate mechanism. There are many artificial or substitution mixtures that pass under the name. *See also* DEGRAS *and* RAISING.

Soffit (*Build.*) (1) The under surface of an arch. (2) The underside of a flight of stone steps. (3) The head lining of an opening. (4) The under horizontal face of an architrave between columns.

Soft (*Silk Manufac.*) Silk from which the natural gum has been removed by a process called "boiling off," in which it loses about 25 per cent. of its weight, and becomes bright and lustrous. *Cf.* SOUPLE.

Soft Brass (*Eng., etc.*) Brass which has been annealed. *See* ANNEALING.

Softener. A large brush used in shading mechanical drawings.

—— (*Paint.*) A large soft brush used for disposing colour evenly, or for blending colours freshly laid on the canvas.

Soft Ground Etching. *See* ENGRAVING AND ETCHING.

Soft Iron (*Eng.*) The term applied in a general sense not only to wrought iron, but also to cast iron, which can be dealt with fairly easily in the lathe or by other machine tools.

Soft Paste (*Pot.*) A term applied to porcelain, the body of which is of a composite character. In its manufacture the greatest heat is given in the

"bisque" (*q.v.*), which is thereby rendered translucent and non-porous. The glaze is fired at a lower temperature, and is therefore a "soft" glaze, lying upon the surface of the body. *See* HARD PASTE, GLOST OVEN, *and* POTTERY AND PORCELAIN.

Soft Soap. A transparent, jelly-like substance made from oil and potash. The oils vary considerably, whale and seal oils, linseed oil, and tallow being sometimes employed, while fish oil is not infrequently used; hence the disagreeable smell which characterises some makes of soft soap. Soft soap is used largely in linen bleaching works, as a basis for insecticides, for greasing the ways of docks, and for domestic purposes. *See* SOAP.

Soft Solder. Solder composed of lead and tin, which has a low melting point and is easily worked with a soldering iron.

Soft Water. Water free from the salts of calcium, etc. *See* CALCIUM COMPOUNDS, CLARK'S PROCESS, *and* WATER.

Soft Woods (*Carp.*) This term, as applied by carpenters and joiners, usually includes the coniferous woods—firs, pines, etc.; but the term is not used in an exact sense.

Soh (*Music*). The fifth degree of the scale in "movable doh" system.

Soil, Formation of (*Geol.*) Soil is usually a mixture, in variable proportions, of clay and sand, often with rock fragments, and with more or less organic matter, chiefly of vegetable origin. Soils are primarily due to the decomposition of rocks in general, and have been brought into their present position by the separate or combined action of a large number of natural causes. Amongst these causes the influence of gravitation plays the most important part. The transporting agents include: (*a*) Water in motion, which gives rise (1) to "rain wash" on a hill slope, (2) to lacustrine deposits, (3) to flood loam on the plains, and to other initial forms of soils. (*b*) The action of the wind in transporting dust from one locality to another, where it may be arrested by encountering a damp surface, as may be seen on a small scale in the patches of moss on a wall, or of house-leek on a cottage roof, or it may be temporarily fixed by filtration through vegetation, which checks the velocity of the air current, and thus lessens its transporting power. (*c*) The continual action of worms in bringing up the finer materials from the lower layer of the subsoil and leaving them at the surface. (*d*) Rain, which intercepts large quantities of dust from the lower part of the atmosphere, and deposits these on the surface. In the neighbourhood of large towns great quantities of soot are washed out of the air by the agency of rain, and thence into the soil. Dead vegetable matter forms no inconsiderable portion of many soils. On upland hill slopes facing northward, or otherwise long out of the sunshine, this vegetable matter tends to change into peat, which is an important constituent of many soils in mountain districts.

Soil Pipe (*Plumb.*) The pipe connecting a closet trap with the sewer.

Soils (*Hygiene*). In cold and temperate climates, sands and gravels, if fairly deep and without a substratum of clay, are the warmest and the driest. The next best soils are rocks, such as granites, limestones, and sandstones. Clay soils are cold, and, owing to their impermeability, damp. Pure chalk is permeable; but if mixed with or underlaid by clay, it becomes impermeable and damp. Shallow beds of gravel or sand lying on clay are bad, as they are liable to become waterlogged. *See* SANITATION.

Sol (*Music*). The sol-fa name for G.

Solano (*Meteorol.*) A south-east wind, extremely hot and loaded with fine dust. Peculiar to Spain. The Spanish proverb "Ask no favour during the Solano" expresses its effect on man.

Solar Attachment (*Surveying*). An addition to the theodolite which enables the true meridian to be determined.

Solar Constant (*Astron.*) The number of heat units which a square unit of the earth's surface, unprotected by any atmosphere, and exposed perpendicularly to the sun's rays, would receive in unit time. *See* RADIATION.

Solar Heat (*Astron.*) *See* SOLAR CONSTANT.

Solar Radiation (*Phys.*, *Meteorol.*, *etc.*) The transmission of radiant energy from the sun to the surrounding space, and in particular to the surface of the earth.

Solar Spectrum (*Phys.*) *See* SPECTRUM.

Solar System (*Astron.*) The system in which are included the sun, all the planets with their satellites, and minor planets.

Solar Time, Apparent (*Astron.*) *See* MEAN SOLAR DAY.

Solder. A fusible alloy used to form a joint in certain metals. *See* SOFT SOLDER, HARD SOLDER, *and* SOLDERING.

Solder Dot (*Plumb.*) A small drop of soft solder used to cover the heads of screws employed in fixing sheet lead.

Soldering. Uniting metallic surfaces or forming joints by means of a fusible alloy (*see* SOLDER). The efficiency of soldering depends on the intimate union of the surface of the metal operated upon with the alloy used as a solder. To effect this the surfaces are carefully cleaned, and in most cases a flux is used during the operation, *e.g.* resin or a solution of zinc chloride in soft soldering, or borax in hard soldering. The flux assists in removing oxide, etc from the metal while in the heated state. A suitable quantity of solder is applied to the joint, and fused by the application of a heated soldering iron or the blowpipe flame. As the joint becomes hot, the solder melts, and runs, under the action of surface tension, along the portions which have been prepared and heated to the proper temperature. Soft solder is easily caused to follow the track of the soldering iron as it is drawn along the joint; but hard solder, which always requires the heat of a blowpipe, is more difficult to manipulate, and the surfaces to be soldered require very careful preparation. Solder must of course have a melting point which is lower than that of the metals to be united. *See also* SOLDERING IRON, HARD SOLDER, *and* SOFT SOLDER.

Soldering Iron *or* **Bit.** A tool consisting of a short thick rod of copper, mounted on an iron stem, with a wooden handle. The end of the copper portion, or BIT, is either pointed or chisel shaped. In use the bit is heated, rapidly cleaned, and TINNED or coated at the end with solder, when it is ready to be applied to the joint. *See* SOLDERING.

Soldering Tongs. Tongs with a flat nose, used for brazing the joints of band saws.

Sole. A highly esteemed food fish, *Solea vulgaris*, common to Europe.

Sole *or* **Sole Plate** (*Eng.*) A base or bed plate.

Soleil (*Textile Manufac.*) *See* OTTOMAN RIB.

Solennemente (*Music*). Solemnly.

Solenoid (*Elect.*) A coil of wire wound into the form of a helix; a tubular coil.

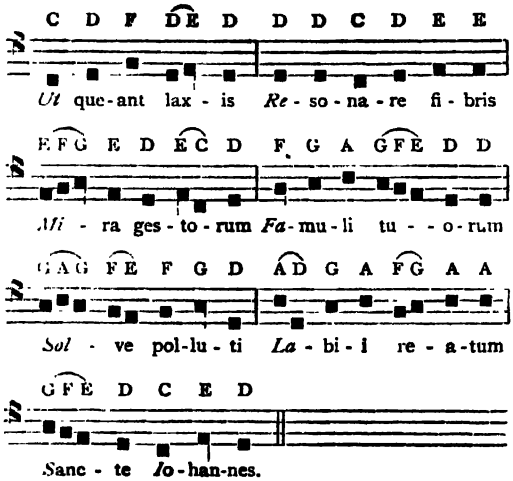
Solenoidal Filament (*Magnetism*). A linear magnet, *i.e.* one whose breadth and thickness are negligible. It may be either straight or curved.

Sole Piece (*Carp. and Join.*) *See* FOOT BLOCK.

Sol-fa (*Music*). Sol-fa-ing is singing notes to syllables instead of words. The syllables are:

(Do) Ut, Re, Mi, Fa, Sol, La, Si.
C, D, E, F, G, A, B.

The first six syllables are supposed to have been invented by Guido d'Arezzo at the beginning of the eleventh century, "as an aid to pupils in learning to read music," and were taken from the first syllable in each division of a festival hymn to St. John the Baptist, the music to which (composed about 770), it will be observed, begins on the six ascending notes of the scale, C to A:



The seventh syllable Si appears to have been added at the beginning of the seventeenth century, and to have been suggested from the initial letter of the two words in the last line, S, I. About the same time Do was substituted for Ut in Italy and England, as being more euphonious, and has been almost universally accepted. The oldest form of Solmisation, *i.e.* the art of using syllables to illustrate the scales, was employing Ut or Do for the Tonic, and we now speak of this as the Movable Do. This mode of using the syllables has the advantage of fixing in the student's mind the relationship of the several notes of the scale, as Tonic, Dominant, Leading note, etc., irrespective of absolute pitch, and of compelling him to determine the different modulations of key in a piece; whereas the Fixed Do depends on absolute pitch, or rather on the study of intervals. *See also* TONIC SOL-FA.

Solfatara (*Geol.*) A volcanic vent amongst the recently extinct volcanoes west of Naples, whence sulphurous and other fumes come forth into the air, and where the products arising from the condensation of these fumes collect in the solid form on the cooler rocks around the vent. These sublimed products include a large number of substances of use in the arts, of which, as the name Solfatara suggests, sulphur is one. Similar vents from which arise emissions of various substances, volatile at a low temperature, are of common occurrence elsewhere in the neighbourhood of dormant and recently extinct volcanoes, to most of which the name solfatara is now usually applied. Hence volcanoes which have quieted down to the condition in which gaseous emissions have taken the place of the normal eruptions are said to have passed to the solfataric stage. The acid fumes give rise to some important modifications of the volcanic materials around the vent.

Solfeggio (*Music*). An exercise for the singing of music to the sol-fa syllables. Amongst the best known of the more easy "solfeggi" may be mentioned Concone's exercises. Solfeggi must not be confused with exercises in vocalisation; the latter consist of singing to one vowel, and not to different syllables. *See* SOL-FA.

Soli (*Music*). One to each part.

Solid. That form of matter in which the molecules lie close together with little freedom of movement, and in which they cannot be separated except by the application of a definite amount of force. Maxwell defines a solid as a body which can sustain a longitudinal pressure without being supported by a lateral pressure.

Solid Angle. Three or more surfaces which intersect at a point are said to form, or to include, a Solid Angle, *e.g.* there is such an angle at the top of a pyramid or at each corner of a cube. The solid angle subtended at a point by any given area is that formed by drawing lines from the given point to every point in the boundary of the area. The magnitude of the solid angle so formed is the area cut off on a sphere of unit radius by the irregular cone formed by the lines.

Solid Drawn Tube (*Eng.*) Metal tubing which has been formed by forcing or drawing the metal in a fluid or plastic condition over a mandrel or series of mandrels; a tube is thus formed which has no joint or seam. Lead, copper, brass, iron, etc., can be thus treated.

Solid Frame (*Carp. and Join.*) A thick frame, with the rabbet and moulding worked on the solid stuff.

Solidification. The process of becoming solid; freezing, crystallisation, etc.

Solid Matter (*Typog.*) Type set without space or leads between the lines.

Solid Rolled Girder (*Eng.*) A girder rolled in one piece instead of being built up. *See* GIRDER.

Solleret (*Arm.*) *See* ARMOUR.

Solmisation (*Music*). *See* SOL-FA.

Solo (*Music*). Alone; a composition for one voice or instrument.

Soloist (*Music*). One who performs alone, either with or without musical accompaniment.

Solo Organ (*Music*). The manual of an organ having stops of a solo character, and imitating as nearly as possible the different orchestral tones, such as flutes, clarionet, orchestral oboe, trumpet, tuba, etc.

Solstices (*Astron.*) The times when the sun is at its greatest distances from the equator. The dates are June 21 and December 22; the day is longest at the first or summer solstice, shortest at the second or winter solstice, in the northern hemisphere.

Soluble Blue. *See* DYES AND DYEING.

Soluble Castor Oil. Generally applied to castor oil that has been hydrolysed with sulphuric acid to make Turkey red oil. It is also applied to castor oil which has been "blown" in its preparation as a lubricant, after which it becomes miscible with petroleum hydrocarbons.

Soluble Glass. A silicate of sodium prepared by fusing sodium carbonate and silica. It has a glassy appearance; hence the name SOLUBLE GLASS, or WATER GLASS. It is used as a preservative for certain limestones, as it combines with the calcium to form an insoluble silicate. It is also used as a mordant in calico printing, for preserving eggs, filling soap, and other purposes.

Solute. A dissolved substance.

Solutions (*Chem.*) "Homogeneous mixtures which cannot be separated into their constituent parts by mechanical means, the proportion between the parts being continuously variable between certain limits, with a corresponding continuous variation in properties" (*Whetham*). The components of any given solution may be elements or compounds, or both, and there is no restriction as to physical state. For example, sea water is a solution of many solids and several gases in the liquid water; many alloys are examples of solid solutions, so also are mixed crystals. A few cases of solution are briefly considered in what follows. GASES IN WATER: All gases dissolve in water, but in very unequal amounts. Thus one volume of water at 0° dissolves 1,270 volumes of ammonia, but only ·0226 volume of hydrogen. When a gas is very soluble in water, chemical change occurs on solution; ammonia, for example, forms the ions $\overset{+}{HN_4}$ and $\overset{-}{OH}$. Again, hydrogen chloride forms the ions $\overset{+}{H}$ and $\overset{-}{Cl}$. Where no action occurs between the gas and water, Henry's Law (*q.v.*) holds; in the case of a mixture of gases, a simple extension of this law holds—every constituent of the mixture behaves as if the others were absent; this is sometimes called the Law of Partial Pressures. The solubility of gases in water diminishes with increase of temperature; by solubility of a gas is meant the volume of the gas divided by the volume of the water in which it is dissolved at any given temperature and pressure. The halogen acids are exceptions to this statement, for starting with a saturated solution of hydrogen chloride, for instance, at 0° and 760 mm., and keeping the pressure constant, the solution changes in strength from about 45 per cent. by weight of hydrochloric acid to 20·24 per cent., as the temperature rises to 110°. LIQUIDS IN LIQUIDS: Some liquids are miscible in all proportions, as alcohol and water; others are partially miscible, as ether and water. When these two are shaken together, enough of each being taken, two layers separate on standing, the upper one being a solution of about 3 per cent. of water in ether, and the lower one a solution of about 10 per cent. of ether in water; others are practically non-miscible, as water and oil, or water and carbon disulphide. In the first case the mixture may boil below the lower boiling constituent, above the higher boiling constituent, or between these two. When the vapour pressure of the mixture attains a maximum value, then, on boiling, a mixture first approximating to and finally attaining the composition corresponding to this maximum vapour pressure will distil over, and that constituent which was in excess will remain behind. An example of this kind is a mixture of propyl alcohol and water. When the vapour pressure of the mixture attains a minimum, then, on boiling, that constituent which is present in excess will distil over, and a mixture will remain behind corresponding in composition to the mixture of minimum vapour pressure. An example of this kind is a mixture of water and formic acid. When the mixture has no maximum or minimum vapour pressure, then, on boiling, the lower boiling mixture will come over first; thus a mixture of water and methyl alcohol can be completely separated by distillation. In the second case (partially miscible liquids) it is clear that if the solubility of one liquid A in another B increases with temperature, while the solubility of B in A diminishes with rise of temperature, then there will be a temperature at which the liquids are miscible in all proportions; this is the case, for example, with aniline and water, which are miscible at 114°, phenol (melts at 42°), and water at 80°. Again, the vapour pressure of a solution of A in B must be equal to the vapour pressure of a solution of B in A, when both solutions are saturated at the same temperature; hence on distilling together the two layers formed by shaking two partially miscible liquids, distillation will proceed at a constant temperature so long as the two layers remain, and the distillate will have a constant composition. The boiling point may be above the boiling point of the higher boiling constituent, below that of the lower boiling constituent, or between the two, according to the degree of miscibility, the difference between the boiling points, and the effect of the vapours on each other. The third case need not be considered. An interesting special case illustrating these cases is the following, due to Professor Young. Alcohol forms mixtures of minimum boiling point (*i.e.* maximum vapour pressure) with water at 78·15° and with benzene at 68·25°, and is miscible with these liquids in all proportions. Benzene is not miscible with water, so that when the two are heated together they boil below the boiling point of benzene, *viz.* at 69·25°. When a mixture in suitable proportions of all three is distilled, a constant boiling fraction of all three might be expected to come over at a temperature below any of the above; then should one constituent be removed in this way the ternary fraction would be followed by a binary fraction boiling below either of its constituents. Lastly, the binary fraction should be followed by that single constituent which was initially in excess. Now, in fact, if a mixture of equal weights of benzene and strong alcohol (93 per cent. by weight alcohol) be distilled in an efficient fractional distillation apparatus, these results are very nearly obtained; the ternary mixture, alcohol, water, benzene, comes over at 64·84°, it is followed by a mixture of benzene and alcohol; and finally alcohol containing only 1·4 per cent. of water and a trace of benzene comes over. On redistilling this last fraction with benzene, absolute alcohol can be obtained. SOLIDS IN WATER: The solubility of a solid in water is expressed in three different ways: (*a*) in ordinary solubility determinations, as grams in 100 grams of water; (*b*) in volumetric analysis, and sometimes in the theory of solutions, as grams in 100 cc. or 1000 cc.; (*c*) commonly in the theory of solutions, as gram molecules per litre; in all cases the temperature is stated or understood to be the ordinary temperature, 15°; the pressure need not usually be stated, as its effect on solubility is very small. Solids differ enormously in solubility in water; *e.g.* barium sulphate, which is for practical purposes insoluble, is only soluble to the

extent of ·00025 grs. in 100 cc. of water at 18°, while at the same temperature 100 grams of water dissolve 203 grams of cane sugar. Ordinarily increase of temperature increases the solubility; thus potassium nitrate increases rapidly in solubility with increasing temperature, while common salt increases very slightly (*see* CURVE, *under* POTASSIUM COMPOUNDS), and sodium sulphate, Na_2SO_4, diminishes in solubility. Solutions of some solids can be prepared which contain more of the solid at a given temperature than the amount of the solvent present in the solution could be made to dissolve if solvent and solid are shaken together at this temperature, no matter how long the shaking is continued; such solutions are called supersaturated. Let 100 grams of water be boiled with sodium sulphate till it can take up no more of the salt; now filter into a perfectly clean flask, and plug the neck of the flask with cotton wool; even when the solution has cooled to 15°, no crystallisation will have occurred. If a crystal of sodium sulphate be dropped in, crystallisation begins at once, and the salt separates out with evolution of heat; when the system has cooled again to 15°, it will consist of sodium sulphate and a saturated solution of sodium sulphate. These supersaturated solutions differ in no way except stability from unsaturated solutions, and they are formed in virtue of what may be called phase inertia. When a substance undergoes solution, contraction usually occurs; that is, the volume of the solution is less than the sum of the volumes of substance dissolved and of the solvent used to dissolve it; also when a solution is diluted with more of the solvent, there is usually a contraction. If in making salt solutions, chemically equivalent quantities of salts are made up to the same volume, certain relations appear between the densities of the solutions. Suppose normal solutions are used and two bases are fixed on, say, potassium and ammonium, then whatever acid these bases are combined with, there will be a constant difference between the densities of the normal solutions KA and NH_4A, where A stands for the acid. A similar statement holds for acids. Therefore, by taking the densities of a comparatively few normal solutions of salts, it is possible to calculate the density of any normal solution. Example: The densities of normal ammonium and potassium chlorides are 1·0157 and 1·0444; the difference is 0·0287; the density of normal ammonium bromide is 1·052, or 0·0363 more than the chloride. Therefore the density of normal potassium bromide is (1·0157 + 0·0287 + 0·0363) = 1·0807, the actual value being 1·08. The density of normal ammonium chloride is taken as the standard, and the numbers added to it are *Valson's moduli* for potassium and bromine respectively. Substances soluble in water may be divided into two classes: (I.) Those that give solutions which conduct a current of electricity and are thereby decomposed: (II.) Those which do not conduct a current of electricity. Class I. is found to consist of acids, bases, and salts. The reason why members of this class conduct and are thereby decomposed is that they are resolved on solution into ions (*q.v.*), which under the influence of the current are driven, at speeds which for a given potential difference and temperature are characteristic for each ion, to the electrodes, and there give up their charges. The fate of the ion when it gives up its charge depends on the nature of the ion; if it is not readily attacked by the solvent, it will be deposited at the electrode as a solid, or will escape there as a gas; if it is attacked by the solvent, then chemical action will occur at the electrode. Example: When copper sulphate dissolves in water it decomposes in whole or part, according to the equation $CuSo_4 \rightleftarrows \overset{2+}{Cu} + \overset{2-}{SO_4}$. On sending the current through this solution undecomposed molecules take no part as carriers of the current; but the copper ions are driven to the negative electrode at a speed characteristic for them, and there they lose their charge, and are deposited as metallic copper, while the SO_4 ions are driven to the positive electrode at a speed characteristic for these and different from that of the copper ions, and at the electrode they are deprived of their charge; but the group SO_4 is not set free—it attacks the electrically neutral water molecule, setting free $2\overset{+}{H}$ and appropriating the charge on the oxygen which is liberated, and thus reproducing the SO_4 ion $\overset{2-}{SO_4}$; that is, sulphuric acid is formed at the anode. A salt or acid on solution does not always form simple ions; many irregularities in the conductivity for electricity of salt solutions are accounted for by the formation of complex ions; these complex ions are generally formed by the union of simple ions with undissociated molecules: for example, in the case of cobalt chloride at great dilution it ionises thus:

$CoCl_2 \rightleftarrows \overset{2+}{Co} + 2\overset{-}{Cl}$, but in strong solutions the actions

$$\overset{-}{Cl} + CoCl_2 = \overset{-}{CoCl_3} \text{ and } 2\overset{-}{Cl} + CoCl_2 = \overset{2-}{CoCl_4}$$

probably occur. As the ions are the carriers of the current, the conductivity (by conductivity may be understood molecular conductivity—that is, the reciprocal of the resistance, expressed in ohms, of a solution containing one gram molecule of the dissolved substance contained in a rectangular vessel, two opposite sides of which form the electrodes and are one centimetre apart, while the other sides are nonconductors; the temperature must be constant and specified) of a strong solution should increase on dilution to a maximum corresponding to complete ionisation, and this corresponds with observation. Another deduction to be drawn from the ionic view of solutions is that the ordinary reagents used in qualitative analysis are reagents for ions; when one tests for a chloride in a solution by means of a solution of silver nitrate, then one is really testing for chlorine ions; so that although potassium chloride and potassium chlorate each contain one atom of chlorine in the molecule, only the former will react with silver nitrate to form silver chloride, for these salts form ions in accordance with the equations

$$KCl \rightleftarrows \overset{+}{K} + \overset{-}{Cl} \text{ and } KClO_3 \rightleftarrows \overset{+}{K} + \overset{-}{ClO_3}.$$

It is clear that both salts will give the reactions for potassium. The law of mass action (*see* MASS ACTION) applies to a solution which contains undissociated molecules and ions. Suppose a solution of common salt is precipitated by an equivalent solution of silver nitrate, then we have the reaction

$$\overset{+}{Na} + \overset{-}{Cl} + \overset{+}{Ag} + \overset{-}{NO_3} = AgCl + \overset{+}{Na} + \overset{-}{NO_3};$$

but this is not all, for silver chloride is slightly soluble in water, so there will remain some silver and some chlorine ions not precipitated, and a few undissociated silver chloride molecules. Now these ions will be in equilibrium with undissociated silver chloride, and the latter will be kept at constant concentration by the precipitate; hence we must have (law of mass action) $pq = kr$, where p and q are the concentrations of the silver and chlorine ions, and r

that of the silver chloride; but kr is constant, and therefore pq must be constant; pq is called the SOLUBILITY PRODUCT in this case. If in the above case we desire to precipitate all the silver, or as nearly as possible all of it, then a *slight* excess of sodium chloride must be added so as to increase q; for in this case, as pq is to be constant, then as q is increased, p must be diminished—that is, a little more silver will be thrown out of solution. One more consequence of the ionisation theory may be given. If one and the same coloured ion be united to a number of different colourless ions to form salts, then these salt solutions at sufficient and equivalent dilution should show exactly the same absorption spectrum, namely, that of the coloured ion. Ostwald examined about 300 salts to test this deduction from the ionisation theory, and in every case found the theory confirmed; thus thirteen different permanganates all gave absolutely the same absorption spectrum. To Class II. belong mostly neutral substances such as sugars, and a very few salts such as mercury cyanide. The same idea of a resolution into parts of the molecules of acids, bases, and salts in solution is forced upon us by the phenomena of osmotic pressure (*q.v.*), and the correlated phenomena of lowering of the freezing point and raising of the boiling point of solutions. Suppose 342 grams of cane sugar are dissolved in water and made up to 22·22 litres, then at 0° this solution will have an osmotic pressure of 760 mm. of mercury; 342 is the molecular weight of cane sugar, and 22·22 is the number of litres occupied by 2 grams of hydrogen at 0° and 760 mm., and 2 is the molecular weight of hydrogen. It thus appears as if in a dilute solution of cane sugar the sugar molecules behave like gaseous molecules. Mercuric cyanide shows the same behaviour as cane sugar—that is, a solution containing one gram molecular weight of the salt (252 grams) in 22·22 litres, has at 0° an osmotic pressure of 760 mm. When the osmotic pressure of a solution of common salt is determined by the use of vegetable cells (*see* SEMI-PERMEABLE MEMBRANES), it is found that for a concentration corresponding to that of the sugar—one gram molecule in 22·22 litres—it is double the osmotic pressure of the sugar, thus indicating that each salt molecule is resolved into two particles, each behaving like a single molecule. All strongly dissociated binary electrolytes behave like sodium chloride; the particles into which the osmotic pressure observations indicate that they break up are ions. Substances like calcium chloride, which break up at great dilution into three ions—$CaCl_2 = \overset{2+}{Ca} + 2\overset{-}{Cl}$—have an osmotic pressure three times that of a cane sugar solution of like concentration. It will be seen that if osmotic pressures could be readily determined experimentally, that we should have a valuable means of finding molecular weights, for working at 0° with 2·222 litres of water containing a known weight of the substance the osmotic pressure would be found; it could then be calculated by simple proportion what amount of substance would give an osmotic pressure of 76 mm., and this would be one-tenth of the molecular weight. As this cannot be done, molecular weights are determined by observations of the lowering of the freezing point and raising of the boiling point of solutions. The connection between these and osmotic pressure has been determined both experimentally and theoretically. The experimental basis of the freezing point method is, in the case of aqueous solution: 1 gram molecule of a substance dissolved in a litre of water lowers the freezing point by 1·85°, if there is no dissociation. Boiling point determinations are made where water and a few other common solvents are not available and when a check is desired; ether is a common solvent in boiling point determinations, and for this solvent we have: 1 molecule of the substance dissolved in 99 molecules of ether raises the boiling point of the ether by 0·284°. For the practical method of freezing point determinations, *see* FREEZING POINT. SOLID SOLUTIONS: Examples of these are mixed crystals, such as are formed by crystallising mixed solutions of two isomorphous salts; a number of alloys, such as copper tin and iron carbon; glass of every kind. These are investigated chiefly by means of the Phase Rule. For further information on solutions—which is a huge subject—special works must be consulted, such as *The Theory of Solution* (Whetham), Van t'Hoff's *Lectures on Theoretical and Physical Chemistry*, and *Introduction to Physical Chemistry* (Walker). W. H. H.

Sonata (*Music*). A composition of from two to four different movements, generally three or four. The sonata may be said to have originated from the suite or partita, which were sets of dance tunes in one key, grouped together to form one complete piece. From the suites of Corelli and kindred musicians, composers led gradually to a more fixed key-tonality and showed the need of modulating and fixing the new key in the mind, and of closing the first section in that new key, and also of a greater balance between the two keys. Enlargement of each half of this first section and greater modulation followed, and a new subject was introduced with the new key. With Haydn and Mozart these characteristics are found firmly established, and two subjects, *i.e.* two distinct sets of themes or phrases, in related keys, appear. In their works they added to the three movements, *viz.* a quick, a slow, and another quick one, a fourth, consisting of the minuet and trio. This new movement was placed after the slow movement in the symphony. Beethoven found the sonata in a high state of perfection of design, and to it he added a still higher scheme of design and expression. The old unequal temperament was now dying fast and giving way to the new scale of twelve nearly equal semitones, and with this change came the enlargement of harmonic combinations and possibilities in the matter of modulations. Beethoven added the fourth movement of the symphony mentioned above to the sonata, afterwards altering the minuet to a Scherzo, which in form is the most free of all the sonata movements. He introduced also a much greater variety of key tonality, and bequeathed the sonata to us in that state of perfection which has served as the model down to the present time. Sonatas are compositions for one or two instruments; when for more than two they are called TRIOS, QUARTETS, etc., and if for an orchestra they are called SYMPHONIES, and the sonata form (*q.v.*) is more extended. The usual movements of the modern sonata are: (1) Allegro · (2) Slow; (3) Scherzo, or Minuet and Trio; (4) Rondo, or some other quick movement.

Sonata da Camera (*Music*). A chamber sonata; a secular sonata.

Sonata da Chiesa. A church sonata; a sonata for the organ.

Sonata Form (*Music*). The name given to the plan of design to which the first movement (at times other movements) of a sonata is generally written.

It is also known as First Movement Form; and as Binary Form, from its being in two parts. This form consists of the following:

First Part: "ENUNCIATION" or "EXPOSITION."

INTRODUCTION (optional).

PRINCIPAL SUBJECT in key of Tonic,

"BRIDGE" or Episode leading by modulation to the SECOND SUBJECT in key of Dominant or some other related key (should key of Principal Subject be minor, the Second Subject is generally in key of Relative major or sometimes Dominant minor).

A CODETTA in this new key ends first part with a double bar, either with or without repeat sign. The codetta is not invariably added.

Second Part: consisting of (*a*) DEVELOPMENT or FREE FANTASIA, (*b*) RECAPITULATION.

(*a*) WORKING OUT or developing of material in first part by numerous devices in various keys different from those used in the Enunciation, eventually leading back to

(*b*) RECAPITULATION of First Subject in key of Tonic,

"BRIDGE" or Episode leading away from and back again to key of Tonic.

SECOND SUBJECT in key of Tonic (when Second Subject in Enunciation is in Dominant minor, it is in Tonic major here).

A CODA is generally added to bring the whole to a close.

Sonometer (*Sound*). An instrument consisting of one or more wires or strings mounted on a base or sounding box so as to be capable of longitudinal vibration. Used for experiments on the pitch of notes and its relation to the length, mass, and tension of the vibrating strings.

Sonore, Sonoro (*Music*). Sonorous, resonant.

Soot. Unburnt carbon, from smoke; it also contains various other constituents (*e.g.* nitrogenous compounds) which render it valuable as a manure.

Sopra (*Music*). Above, before, *e.g. come sopra*, as before.

Soprano (*Music*). The highest of women's or boys' voices.

Soprano Clef (*Music*). The C clef on the first line. *See* STAVE.

Sopwith's Staff (*Surveying*). A staff used in levelling; its special feature is the clearness of the graduation, which enables it to be read at considerable distances through the telescope of a level.

Sordini (*Music*). Mutes; dampers. The mute has already been described under MUTE. It may be added that another method of muting brass instruments (as, for example, the horn) is by inserting the right hand into the "bell," thus three-quarters closing it. This, however, raises the sound half a tone, and necessitates transposing the music a semitone lower. In pianoforte music *con sordini*, with dampers, means that the right pedal is *not* to be used, and *senia sordini*, without dampers, that the right pedal *is* to be used. *See also* PIANOFORTE, p. 430, *and* UNA CORDA.

Sorting (*Textile Manufac.*) The operation of classifying the wool of the fleece according to quality and length of staple.

Sorts (*Typog.*) A term applied to the different letters in a case (*q.v.*)

Sostenuto (*Music*). Sustained; giving to each note its full value.

Sotto Voce (*Music*). Under the voice; in a somewhat hushed manner.

Sound. The study of phenomena which are detected by the sense of hearing, or which are of the same nature as these; the phenomena termed sounds are produced and transmitted by the vibrations of particles of matter. Sounds obey the ordinary laws governing the transmission of radiant energy in general; they can be reflected, refracted, etc.

—— (*Music.*) A musical sound is due to regular vibration. Its three qualities are: (1) intensity, due to the extent of the vibration; (2) pitch, due to the rapidity; (3) timbre, *i.e.* its quality, as distinguished from intensity and pitch, due to the form. Sounds are represented on paper by NOTES (*q.v.*) The length of a sound is shown by the shape of a note; the pitch of a sound by the position of the note on the staves.

Sound Board (*Music*). Another name for the belly in stringed instruments. *See* VIOLIN, p. 427. In the organ it is the upper part, or cover, of the wind chest. *See* ORGAN, p. 439. In the pianoforte it is the broad piece of wood under the strings and connected with them by the bridge, over which they are stretched. Its purpose is to reinforce the tone of the strings.

Sounder (*Elect.*) A telegraphic receiver capable of producing two distinct sounds by which the dot and dash of the Morse Code may be represented, the operator reading the message by ear. The sounds are produced by the armature of the electro-magnet in moving back and forth between its stops.

Sound Holes (*Music*). The two *f*-shaped openings in the belly or Sound Board (*q.v.*) of stringed instruments; they allow the belly to vibrate.

Sounding Board. *See* ABATVOIX.

Sound Post (*Music*). A wooden peg of pine which is placed a little behind the foot of the bridge on the treble side of stringed instruments. Its functions are to support the belly during the tension of the strings on the bridge, and to transmit the vibrations of the belly and bridge to the back of the instrument.

Sound, Velocity of. The velocity of sound in any medium is given by the general formula

$$\text{Velocity} = \sqrt{\frac{\text{Elasticity}}{\text{Density}}}$$

In the case of gases the adiabatic value of the elasticity must be taken. *See* ELASTICITY OF GASES. If v be the velocity in cms. per sec., P the pressure of the gas in dynes per sq. cm., γ the ratio of the specific heats of the gas, and ρ its density in grams per cubic cm., then

$$v = \sqrt{\frac{\gamma P}{\rho}}$$

Souple (*Silk Manufac.*) Silk from which about half the natural gum has been discharged, its weight being thus reduced by about $12\frac{1}{2}$ per cent. The dull appearance of raw silk is retained, but the hard feel removed. *Cf.* SOFT.

Sourdine (*Music*). (1) A stop on HARMONIUMS (*see* p. 443). (2) A MUTE (*q.v.*)

Souring (*Leather Manufac.*) The treatment of leather with acid, previous to dyeing or finishing, in order to bleach and cleanse the skin from stains. Souring with sulphuric acid has been proved to be very injurious. Latterly weak organic acids have been substituted.

—— (*Textiles, etc.*) Generically, the process of exposing textures to the action of dilute acid. In

the process of bleaching textile fibres or fabrics the goods are treated with a solution of chloride of lime and then with a dilute solution of sulphuric acid, which sets free the chlorine, bleaches the cloth, and also neutralises the alkalis.

South *or* **South Seeking Pole.** That pole of a magnet which points towards the South Pole of the earth when the magnet is freely suspended.

Southing (*Astron.*) The transit (*q.v.*) of a star or any other celestial body to the south of the zenith.

Sow (*Met.*) The main channel or receptacle through which molten iron flows from a melting furnace to the pig moulds. *See* FEEDER.

Space (*Music*). The alternate degrees of the stave between the lines are called spaces.

Space Box (*Typog.*) A small flat box or tray, divided into about six or eight compartments to contain the various spaces used in justifying lines of types. It serves a useful purpose in correcting matter.

Space Pass (*Textile Manufac.*) *See* ENTERING.

Spaces (*Typog.*) *See* TYPES.

Spall (*Build.*) A small chip off the edge of a stone.

Span. The width of an arch, girder, roof, etc., between the bearing surfaces. *See also* ARCH.

Spandrel *or* **Spandril** (*Architect.*) A triangular space such as the irregular triangular wall space which occurs between the outer mouldings of two adjacent arches and the horizontal line joining their highest points.

Spanish School of Painting. *See* PAINTING, SCHOOLS OF.

Spanner (*Eng.*) A tool used for turning nuts. The nut fits into a short slot, usually formed by two jaws, open at one end. In adjustable spanners the width of this slot can be varied to suit different sizes of nut. In some fixed spanners a hole the shape of the nut is provided, instead of a slot with parallel sides.

Spar (*Min.*) A miner's term for any glittering mineral; generally confined to those which are crystallised, but not necessarily to those which are white or colourless.

Spare Parts (*Eng., etc.*) Duplicates of those parts of a machine which are liable to injury or which quickly wear out are often supplied, especially in the case of machines which are used at some distance from a repairing shop.

Spar, Iceland (*Min.*) *See* CALCITE *and* ICELAND SPAR.

Spark (*Elect.*) The visible and usually audible phenomenon accompanying a sudden electric discharge.

Spark Arrester (*Eng.*) A perforated cap placed over the chimney of an engine used for agricultural purposes or in the neighbourhood of dry timber, etc., to prevent pieces of burning fuel from escaping.

Spark Gap (*Elect.*) A space between two terminals across which an electric spark passes.

Sparking of Dynamos, etc. (*Elect. Eng.*) The production of sparks at the tips of the brushes, due to defective design or incorrect adjustment of the brushes.

Spartalite (*Min.*) A synonym for Zincite (*q.v.*)

Spathic Iron Ore (*Min.*) A synonym for Chalybite (*q.v.*)

Spatula. An instrument shaped like a paper knife, paddle, spoon, or trowel, according to its purpose, and made of bone, metal, or other suitable material. Used by chemists, enamellers, sculptors, etc.

Spear (*Arms*). A weapon consisting of the characteristically shaped head attached to the end of a wooden shaft. Designed for thrusting and throwing. Spears were amongst the earliest of weapons, and were used notably by the ancient Greeks. *Cf.* JAVELIN *and* LANCE.

—— (*Mining*). A term applied to the vertical rods driving the pumps used for draining a mine.

Species (*Biol.*) A subdivision of a GENUS, including all the members of a group of individual organisms which have certain characters in common. "The members of a species are fertile *inter se*, but not usually with members of another species" (J. A. Thomson). *Cf.* GENUS *and* ORDER.

Specific Conductivity (*Elect.*) The reciprocal of the SPECIFIC RESISTANCE (*q.v.*)

Specific Gravity (*Phys.*) The ratio between the density of a body and the density of a substance chosen as a standard. The specific gravity of solids and liquids is given in terms of water. In this case the specific gravity is the ratio between the mass of any volume of the substance and the mass of an equal volume of water.

Specific Gravity Flask (*Phys.*) *See* PYKNOMETER.

Specific Heat (*Phys.*) The ratio between the quantity of heat necessary in order to raise a given mass of any substance through a given difference of temperature, and the quantity of heat necessary to raise the same mass of water through the identical difference of temperature, is the (average) specific heat of the substance between those temperatures. The specific heat may be more simply, though less accurately, expressed as the number of heat units required to raise unit mass of a substance through one degree.

Specific Heats of Gases (*Phys.*) The amount of heat necessary to raise unit mass of a gas through one degree depends upon the conditions under which the gas is heated. If the gas be not allowed to expand, the heat required to raise unit mass one degree is termed the SPECIFIC HEAT AT CONSTANT VOLUME; this is usually represented by C_v. If the gas be allowed to expand while being heated, then external work is done, and the specific heat is increased by the amount of heat which is equivalent to the external work performed. If the gas be allowed to expand while being heated, at such a rate that its pressure remains constant during the operation, the heat absorbed is termed the SPECIFIC HEAT AT CONSTANT PRESSURE; it may be denoted by C_p. The ratio of C_p to C_v depends on the nature of the molecule of the gas.

Specific Inductive Capacity (*Elect.*) The ratio between the capacity of a condenser, of which the plates are separated by a given medium (*e.g.* sulphur, mica, paraffin wax, etc.) and that of a condenser similar in form and dimensions, whose plates are separated by air, is termed the SPECIFIC INDUCTIVE CAPACITY of the medium, which is generally denoted

by K. The value for some common substances is as follows:

Ebonite	1·92
Paraffin wax	2·29
Sulphur	3·97
Mica	6·64
Glass.	6·5 to 7·5.

The value for gases is very nearly unity, but increases as the pressure of the gas is increased.

Specific Resistance (*Elect.*) If r be the resistance of a conductor of length l and cross section a, then

$$r = \sigma\frac{l}{a}$$

The quantity σ is termed the Specific Resistance of the material of which the conductor is made; it is the resistance which the conductor would have if its length and its cross section were both unity. The approximate value of σ for some common materials (taking the centimetre as the unit of length) is as follows:

Silver	1·5	microhms.
Copper	1·6	,,
Aluminium . . .	2·9	,,
Iron	9·6	,,
Lead	19·5	,,
Mercury	94	,,

Specific Volume (*Phys.*) The volume of unit mass of a substance, usually expressed in cubic centimetres per gram.

Specimen Bar (*Eng.*) A bar of metal prepared for testing in the testing machine.

Specimen Holder (*Eng.*) A form of clip by which the ends of a specimen are held in the testing machine.

Specimen Page (*Typog.*) When a new work is about to be put in hand it is customary for the printer to prepare and submit a proof or specimen, showing the proposed size of page, style of type, general arrangement, etc.

Spectra. *See* SPECTRUM *and* SPECTRUM ANALYSIS.

Spectre of the Brocken (*Meteorol.*) An optical effect. Travellers standing at sunrise on the summit of the Hartz mountains see a magnified image of their shadows thrown upon the mists or clouds by the sun at their backs.

Spectrograph (*Astron.*) A form of Spectroscope (*q.v.*) adapted for photographically recording spectra.

Spectroheliograph (*Astron.*) A form of instrument for photographing the sun in monochromatic light, or in light of any particular wave length.

Spectroscope (*Phys.*) An instrument for the production and examination of spectra. In a typical form the light which it is desired to examine is first formed into a parallel beam by the COLLIMATOR. This is a tube, carrying a lens at or near one end, and at the other, which is directed towards the source of light, an adjustable SLIT. The latter lies in the focal plane of the lens, so that light diverging from the opening emerges from the lens as a parallel beam, and then falls upon a Prism (or train of prisms) or upon a Diffraction Grating (*q.v.*) After passage through the prism, the light traverses a telescope placed so that the whole beam is received by its object glass; on looking into the telescope, the spectrum is seen. The telescope can be turned about a vertical axis passing through the centre of the table of the instrument, so that it can be adjusted to view the slit directly through the collimator when the prism is removed, or can be so placed as to observe any particular portion of the spectrum. A circular divided scale is attached to the stand, and a vernier is carried by the arm of the telescope, so that the angle of deviation of any given line in the spectroscope can be accurately measured. (If this divided scale is carried nearly, or completely, round the table of the instrument, the latter is usually termed a SPECTROMETER, and may be used for measurements other than those of a spectrum, *e.g.* for measuring the angles of a prism.)

A DIRECT VISION spectroscope is one in which the axis of the telescope is in the same straight line as the axis of the collimator; in this case the whole instrument may be contained in a single tube, without any stand or scale. It is necessary in this case to produce dispersion without deviation of the mean rays or axis of the beam of light; this may be accomplished by a suitable combination of prisms (*e.g.* three of crown glass and two of flint glass), or by a combination of a diffraction grating and a prism.

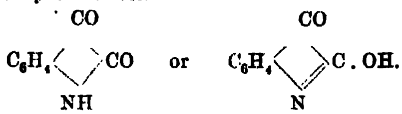
The relative positions of the lines of a spectrum may be observed in several ways. (1) The angular deviation of each line may be read off on the scale and vernier described above, a pair of cross wires in the eyepiece being brought into coincidence with each successive line. (2) A linear scale may be fitted so as to be viewed through the eyepiece simultaneously with the spectrum under observation and the positions of the lines relatively to the divisions of the scale noted. (3) The spectrum may be photographed by causing the beam to enter a suitable camera instead of observing the spectrum through the telescope.

Spectrum (*Phys.*) If a beam of white light be refracted through a prism and then received on a screen, it is seen to be drawn out (DISPERSED) into a brilliantly coloured band, which is termed a SPECTRUM. The colours merge gradually into each other, but it is easy to distinguish approximately seven regions whose colours are respectively Red, Orange, Yellow, Green, Blue, Indigo-blue, Violet. The deviation is least in the case of the red rays, and gradually increases as the violet is approached. Further investigation shows that the dispersion or separation of the constituents of the original light is not confined to the regions forming the VISIBLE SPECTRUM. There are present invisible rays which are less deviated than the red, and which are termed the INFRA-RED RAYS, and also others which are more deviated than the violet, termed the ULTRA-VIOLET RAYS. The former are most easily observed by their thermal effects, detected by a thermopile or bolometer; the latter by the aid of photography. The invisible parts of the spectrum which have thus been investigated are of much greater extent than the visible portion, extending from ultra-violet light of wave length about ·00001 cm. to nearly one hundred times that length; while the visible spectrum only includes light of wave length lying between ·00004 and ·00008 cm. If light of any particular wave length be absent from the original beam, a dark line appears in the spectrum. The solar spectrum contains a number of these dark lines, which are termed FRAUNHOFER LINES. A spectrum which is unbroken by lines is termed a CONTINUOUS SPECTRUM, as distinguished from a LINE SPECTRUM, in which they occur. A third type of spectrum is

termed a FLUTED SPECTRUM, in which a banded appearance is given by a number of fine lines arranged in groups. *See also* SPECTRUM ANALYSIS.

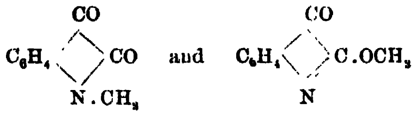
Spectrum Analysis (*Chem.*) The light emitted by an incandescent gas is characteristic for that gas: but the light must be examined in the spectroscope (*q.v.*), where it can be seen arranged in the order of the wave lengths of its component colours, that is, its spectrum (*q.v.*) must be seen. For example, if a sodium compound is put on a platinum wire, and held in a Bunsen flame, some of the compound is volatilised and decomposed, the sodium vapour emits a yellow light, and this, when viewed in the spectroscope, shows two yellow lines, very close together, of wave length 5,896 and 5,890. (The unit of length is 1×10^{-7} mm. = one tenmillionth of a millimetre, which is called the Ångström unit.) No element besides sodium gives this spectrum. The Bunsen flame has not the highest temperature that it is possible to command; both that of the electric spark and of the electric arc are higher. When a sodium compound is volatilised in either of these, it gives the two yellow lines mentioned above, and many other lines as well. Elements (for example platinum) which are not gasified in the Bunsen flame, and therefore give no spectrum, give spark and arc spectra. The spectrum of a gas is obtained by enclosing the gas in a glass tube, provided with two platinum electrodes, exhausting the tube to a suitable degree, and sending the current from an induction coil through the rarefied gas; the light examined in the spectroscope gives the spectrum of the gas. By one or other of these methods every element can be made to give a spectrum, and every element has its own spectrum, composed of light of wave lengths peculiar to that element. The spectra of all the elements have been "mapped," that is, the wave lengths of the lights they emit have been tabulated, for the Bunsen flame, the spark obtained from an induction coil with and without the use of Leyden jars, and for the arc. Should the spectrum of a supposed element be examined, it is possible to pick out some of the more prominent wave lengths in its spectrum, and compare them with those of all the known elements, and in this way to tell whether a known element is being dealt with. Thus, when the Curies were isolating radium, they submitted their preparations to an expert spectroscopist (Demarçay), and "the results of the spectrum analysis brought conviction to us when we were still in doubt as to the interpretation of the results of our research." The first new line found by Demarçay was 3814·7 (Å.u)—a line just in the ultra-violet. (N.B.—The extent of the spectrum visible to the eye is from about 6,500 in the red to 3,900 in the violet.) Many elements have been discovered by means of their spectra, *e.g.* Cæsium, Rubidium, Thallium, Indium, Gallium, and Helium. A compound of an element does not always give the spectrum of the element in the Bunsen flame; the compounds of the alkalis give the spectra of the alkaline metal, but compounds of the alkaline earths, calcium, strontium, barium, give spectra containing few lines of the metal and more of the compound employed, or the oxide of the metal. Flame spectra are best obtained from halogen salts of the metal: a non-volatile salt should be converted into chloride. In spark spectra the halogen salts give the metal lines. The number of lines in the spectra of the various elements varies enormously; for instance, from a dozen in lithium to about 4,500 in iron. The number varies also with the temperature, for while thallium gives one line in the Bunsen flame, it gives about 24 in the arc. Relationships are gradually being discovered between the lines of one and the same element, and between lines of chemically related elements. For example, a formula of the type $\frac{1}{\lambda} = A - Bn^{-2} - Cn^{-4}$, when the constants are properly chosen from a few lines, will give with more or less accuracy a fair proportion of the remaining lines. In the case of hydrogen the formula becomes $\frac{1}{\lambda} = A - 4Am^{-2}$, where $A = 27418{\cdot}75$, and m is in succession 3, 4, 5, etc., and it gives many of the lines very accurately. Again, in the case of many elements the lines fall into series, a principal series of sharp lines, a first and second subordinate series of less sharp lines. A modification of the typical formula has to be used for each series. The lines of a related series of elements are often related, *e.g.* the lines of sodium, potassium, rubidium, cæsium run in doublets, those of magnesium, zinc, cadmium run in triplets. In some cases it is possible to calculate approximately the atomic weight of an element in a related series, when the relations of the lines of the various series to the lines of the various series of its related elements have been established. When light passes through a substance, some of it is absorbed; if the substance exerts a SELECTIVE ABSORPTION for light of definite wave lengths, then the light transmitted will be characteristic, under proper conditions, for that substance, and an examination of the transmitted light in the spectroscope will show dark bands in its spectrum corresponding to the wave length of the light absorbed by the substance. The bands are called ABSORPTION BANDS, and their nature, position, and extent for a given thickness of the substance, serve to identify the substance. The dark lines in the solar spectrum are due to absorption. An incandescent gas absorbs precisely those rays which it emits at the same temperature (Kirchhoff). Thus, when a sodium compound is held on platinum wire in front of the slit of a spectroscope, the two yellow sodium lines are seen. Now if a strong white light is brought behind the sodium light, a continuous spectrum is seen, except for two dark lines, which cross it exactly where the two yellow lines were before. The vast number of dark lines which appear in the solar spectrum (Fraunhofer lines) are due chiefly to elements which exist in the atmosphere of incandescent gas which surrounds the sun and which exercises selective absorption on the rays of every wave length issuing from the incandescent mass of the sun below. The Fraunhofer lines are produced by about thirty-six elements, which occur on the earth. A few of the dark lines of the solar spectrum are due to the absorptive action of the earth's atmosphere. Some of the lines are due to oxygen and some to water vapour: a group of lines (5,860 to 6,030) near the sodium lines is due to water vapour, and when there is much water vapour in the air this group darkens, and is therefore used to predict rain, and has received the name of the RAIN BAND. Many coloured liquids show absorption bands, and many liquids which appear to us to be colourless show absorption bands in the ultra-violet, and would therefore be coloured to an eye sensitive to the ultra-violet. Most probably an ant would regard benzene as a coloured substance. Among substances which can be easily detected by their absorption spectra are blood (Hæmoglobin, oxyhæmoglobin, carboxyhæmoglobin), very many "aniline" dyes, ultra-

marine, and some precious stones. *See also under* SOLUTIONS. The absorption spectra of a number of tautomeric substances have been examined by Professor Hartley, and he has been able to throw light on the structure of some of these. Example, isatin may be written—



I. II.

It has two different methyl derivatives—



Methylpseudoisatin. Methylisatin.

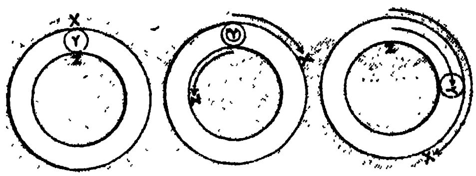
Now the spectra of isatin and methylpseudoisatin closely resemble each other, and both have two bands; the spectrum of methylisatin has a single, strong, absorption band. Hence of the two formulæ for isatin the one marked I. belongs to isatin—at all events in alcoholic solution, in which state the bands were observed. W. H. H.

Specular Iron (*Min.*) A synonym for the crystallised variety of HÆMATITE (*q.v.*), so called because the Roman ladies used the tabular crystals as mirrors.

Speculum. A mirror of polished metal, used by ancient races for the ordinary purposes of a mirror. Concave specula are used in reflecting telescopes. *See* TELESCOPE.

Speed. Velocity or rate of motion applied either to rectilinear or to rotary motion.

Speed Gears (Change) for Cycles. The influences adverse to a cyclist's progression fall under two heads:—I. *Mechanical:* (*a*) Vibration, caused by unevenness of the surface over which the cycle moves; (*b*) friction in the bearings of the machine. II. *Physical:* (*a*) Air pressure; (*b*) gravity. The first two of these have been lessened by the adoption of pneumatic tyres and ball bearings. The second group cannot be reduced, and the only way to minimise their effects on the rider is to use some mechanical device which shall enable him to avoid excessive exertion by sacrificing some speed. The cycle change-speed gears now on the market employ a "sun and planet" epicyclic train of cogwheels to reduce or increase the speed of the drive relative to the normal, or solid, gear. Usually the train is included in the hub of the driving wheel; in a few cases in the large chain sprocket wheel. James Watt is considered to be the inventor of the sun and planet motion, which he used on his steam engines to impart motion from a connecting rod to a flywheel. The "sun" was attached rigidly to the wheel spindle, the "planet" rigidly to the end of the connecting rod, and a bridle link, passing round the central bosses on each cog, kept the two pinions—which had an equal number of teeth—always in mesh. This ingenious contrivance not only transformed the linear movement of the piston rod into a rotatory movement of the flywheel, but also caused the "sun" and flywheel to turn *twice* on their centres while the "planet" circled the "sun" once, since the planet forced the sun to overrun it, as a little reflection will render apparent. In epicyclic cycle gears there is, besides the sun and planet, an exterior annulus with internal teeth, revolving concentrically with the sun. The planet rolls between the two.



SPEED GEARS.

From figs. *a*, *b*, and *c* the action of the train and the data for calculating speed ratios can be gathered. In the figures we have X the outer annulus, Y the rolling pinion or "planet," and Z the fixed pinion or "sun." To understand how this combination works, let us first suppose (fig. *b*) that the axis of the pinion Y is fixed in space, the pinion being, however, capable of rotating about this axis. Further, let us suppose that the "sun" Z and the annular rack X are perfectly free to rotate, and that the number of teeth on Z is t, while the number on X is T. Then if the pinion Y has n teeth, a complete clockwise revolution of Y about its stationary axis will cause n teeth to engage in succession with the teeth of X; and the annular rack will therefore advance by n teeth, or by $\frac{n}{T}$ of a complete rotation in a *clockwise* direction (fig. *b*). At the same time, n teeth of the inner pinion Z must have been engaged in succession, and Z must have rotated through $\frac{n}{t}$ of a complete rotation in an *anti-clockwise* direction. In fig. *c* the sun is stationary, and the axis of Y is free to move. Let us now suppose that the whole arrangement is rotated as a single body about the centre of Z through $\frac{n}{t}$ of a complete clockwise rotation; this will bring the central pinion Z to its original position. The axis of Y will have revolved about the centre of Z through $\frac{n}{t}$ of a complete clockwise revolution, and the rack X will have rotated about the centre of Z through the sum of the angular displacements imparted to it, *i.e.* through $\left(\frac{n}{t} + \frac{n}{T}\right)$ of a complete clockwise motion. Thus:

$$\frac{\text{Angular displacement of X}}{\text{Angular displacement of Y}} = \frac{\frac{n}{t} + \frac{n}{T}}{\frac{n}{t}} = \frac{t + T}{T}$$

From this it is clear that if the central pinion Z is maintained stationary while the annular rack is rotated at any given speed, the pinion Y being free to roll as the conditions require, then while Y rolls once completely round Z, the annular rack X will make $\frac{t+T}{T}$ rotations. Thus we have:

$$\frac{\text{Speed of rotation of X}}{\text{Speed of rotation of Y}} = \frac{t+T}{T}.$$

If the motion of Y is opposed by a given force, and a motive force acts on X, then:

$$\frac{\text{Force acting on X}}{\text{Force opposing motion of Y}} = \frac{T}{t+T}$$

To take an example: if X has fifty teeth and Z

twenty-five teeth, one revolution of the axis of Y about the centre of Z implies $\frac{50+25}{50} = 1\frac{1}{2}$ rotations of X, and, conversely, one rotation of $X = \frac{50}{50+25} = \frac{2}{3}$ revolution of Y. If a given motive force be applied to X, this will be capable of overcoming a force 50 per cent. greater opposing the motion of Y, and the speed of Y will be less than that of X by $33\frac{1}{3}$ per cent. If the force be applied to Y's centre, there will be a speed gain of 50 per cent., and a diminution of force of $33\frac{1}{3}$ per cent. with regard to X. Should X and Z be mechanically connected so as to form a rigid whole, Y obviously can no longer roll round Z. In general, if *any* two of the elements X, Y, and Z are rigidly connected, the combination can move only as a solid body. With a three-element epicyclic gear three gears are possible. The gear may: (1) turn as a whole: (2) it may be geared *up* by transmitting the rider's driving power through the small sprocket wheel to Y, from Y to X, and from X to the spokes of the driving wheel; (3) it may be geared *down* by transmitting the power to X, and through Y to the spokes. These three combinations give the normal, high, and low speeds respectively, as found in the "Sturmey-Archer" gear. In the "Fagan," "Hub," and other well-known gears only two combinations are used, the higher gear being the solid, since it is more generally used. Want of space forbids a detailed description of the methods by which the element Z is rendered fixed or movable, and two elements are locked together. It must suffice to glance at the "Fagan" gear, which has a sprocket working the driving annulus by a Hyde freewheel attachment. The annulus has sixty-four internal teeth, which gear with four planet pinions rotating on pins forming part of the hub shell. The central pinion has twenty teeth. When pulled in one direction along the spindle it is able to revolve freely; but if pressed by a spring in the other direction, engages with the internal teeth of a collar solid with the spindle. In this last position the central pinion is fixed, and the low gear is obtained. To throw in the high or solid gear, the rider, by means of a wire cable, pulls the central pinion free of the toothed collar, and brings it into engagement with teeth on the interior of a central opening in a plate cast solid with the annulus, causing annulus and "sun" to rotate together. With regard to the number of teeth on X, Y, and Z, the empirical rule has been established that the teeth on X must be equal to (teeth on Y × 2) + teeth on Z, whatever be the ratio of the gearing. If X remains constant in size, the difference of velocity of rotation of X and Y about the axis of Z will increase with the decrease in the diameter of Y and the increase in the diameter of Z. As X must be kept conveniently small, and Z yet be sufficiently large to slide on the back wheel spindle, the size of Y relative to that of Z is confined within somewhat narrow bounds; and in most popular two-speed gears a drop of 20 to 25 per cent. from the solid to the low gear is usual. As cycle change-speed gears give only a limited number of ratios, they are compromises which naturally incur criticism. The best proof of the utility of this class of mechanism is found in their increasing adoption by the cycling public. A. W.

Speed Indicator. An instrument for indicating or recording rate of motion, whether motion of translation or of rotation.

Speed of Ignition. The rate at which the explosion or burning of the mixture of inflammable gases occurs in the cylinder of a gas or oil engine.

Speed of Reactions (*Chem.*) Let there be two substances, A and B, which react to form two new substances, A^1 and B^1, and let the substances A^1 and B^1 be capable of reacting so as to reproduce A and B; further, let A and B react molecule for molecule with each other, and A^1 and B^1 react in the same way: then if the system is homogeneous, and p, q, p^1, q^1 are the concentrations of A, B, A^1, B^1 respectively, we have, by the law of mass action (*see* MASS ACTION), for equilibrium, $kpq = k^1p^1q^1$. This implies that the two reactions, the direct and the reverse, are proceeding at the same speed. At a particular moment before equilibrium is reached, the speed will be given by the difference between the speeds of the direct reaction and the reverse reaction; so that if a, β, a^1, β^1 are the concentrations at the beginning of a definite time, and a quantity x gram molecules is transformed in time t, then

$$\frac{dx}{dt} = k(a-x)(\beta-x) - k^1(a^1-x)(\beta^1-x).$$

Now suppose that the reverse reaction occurs to an extent which is inappreciable, the equation becomes

$$-\frac{dx}{dt} = k(a-x)(\beta-x).$$

Put $a - x = C$, and $\beta - x = C^1$, then

$$(1) \quad -\frac{dC}{dt} = kCC^1.$$

If only one substance is present, we shall have

$$(2) \quad -\frac{dC}{dt} = kC.$$

The minus sign occurs because the concentration diminishes while the time increases. Equation (2) gives the speed of a monomolecular reaction, that is, a reaction in which single molecules decompose; equation (1) gives the speed of a bimolecular reaction, that is, one in which two substances react molecule for molecule with each other. More complex reactions are not considered in this article. In the monomolecular reaction, let the concentration at the beginning be C_0, and at the end of a time t, C_t; then on integrating between these limits we get—

$$\log_e C_0 - \log_e C_t = kt.$$

Or, taking logarithms to base 10—

$$\log C_0 - \log C_t = 0{\cdot}4343kt.$$

From this it is seen that $C_t = 0$ when t is infinite, that is, a reaction never comes to an end in a finite time. In practice a reaction is at an end when the concentration of the substance which has undergone change is so small that our tests for its presence fail. As an illustration of a monomolecular reaction, the inversion of cane sugar by a dilute acid may be given—

$$C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6.$$

Here the water which enters into the reaction is so small compared with the whole amount present that it may be neglected, in which case we have a monomolecular reaction. The progress of the reaction can be determined by a polarimeter. Wilhelmy first made this experiment (1850), and he showed that the value of $\frac{\log C_0 - \log C_t}{t}$ was constant within the limits of experimental error during the whole course of the experiment. Another example of this kind of reaction which has been carefully studied and shown to conform to the equation is the decomposition of arseniuretted hydrogen by heat

$AsH_3 = As + 3H$. In the case of the bimolecular reaction we shall assume that the concentrations of the two substances are the same; then, on integrating equation (1) between the same limits as before, we have—

$$\frac{1}{C_t} - \frac{1}{C_0} = C_0 kt.$$

A very important example of this kind of action is the saponification of an ester by an alkali. The case of ethyl acetate and caustic potash in twentieth normal solutions has been thoroughly examined, and in this case $\left(\frac{1}{C_t} - \frac{1}{C_0}\right)\frac{1}{t}$ was again found to be constant. Many factors influence the speed of reactions. Temperature has an enormous influence. Thus in the case of the monomolecular reaction

$$\begin{array}{ccc} CHBrCOOH & & CH.COOH \\ | & = & \| \\ CHBrCOOH & & CBr.COOH \\ \text{Dibromsuccinic Acid.} & & \text{Brommaleic Acid.} \end{array} + HBr$$

which occurs in aqueous solution, a rise of temperature of 86° (15° to 101°) increases the speed over 3,000 times. The solvent has also a great influence; ammonium cyanate is transformed to urea much quicker in an alcoholic than in an aqueous solution. The presence of a third substance has often a very great influence; this kind of influence is called catalytic action, and examples are very numerous. Thus, water in small traces causes many substances to combine which will not combine in its total absence, as oxygen and hydrogen, chlorine and hydrogen, etc., and it causes substances to dissociate which will not dissociate when absolutely dry, as ammonium chloride and mercurous chloride. Platinum black (*see* PLATINUM), enzymes (*q.v.*), are other examples of catalytic agents. Pressure exerts a considerable influence on many reactions; it retards the inversion of cane sugar by hydrochloric acid, but it accelerates the hydrolysis of methyl acetate by the same acid. Diminution of pressure accelerates the oxidation of phosphorus by oxygen. *See also* EXPLOSIVES. W. H. H.

Speed Pulleys *or* **Cones** (*Eng.*) When a machine has to be driven at various speeds, it is commonly provided with a Speed Pulley or Stepped Pulley, which virtually consists of three or four pulleys of different diameters, fixed together to form a stepped cone, and keyed on the shaft. This pulley is driven by a belt from a pulley on the counter shaft, which is of similar construction, but arranged so that its widest end is opposite to the narrowest end of the pulley on the machine. In order that the belt may run properly when placed on any pair of pulleys, the sum of the diameters of the two pulleys must be a constant for each pair. If the belt be crossed its tension will then be perfectly constant, whichever pair it be placed on; it remains approximately constant, however, even if not crossed, provided the two pulleys are not too close together.

Spelter (*Met.*) (1) Ingots of zinc. (2) An alloy of copper and zinc, used in brazing.

Spent Oxide. *See* COAL GAS *and* SULPHURIC ACID MANUFACTURE.

Spermaceti. This is perhaps best described as "whale oil stearine," as considerable quantities are obtained from blubber and sperm oils by chilling and expressing, in the same way as stearine (*q.v.*) is obtained. Chemically, it is essentially cetyl palmitate. The name itself is misleading, as it was originally thought to be whale spawn, and thus was named *Sperma ceti*. The chief source is the "head matter" of the *Physeter macrocephalus*, but it is also obtained from the oils of many other cetacea. After "bagging" and pressing to separate the fluid oils the sperm cake is melted, re-pressed, and refined with a potash ley to remove colouring matter and free fatty acids, yielding a white glistening mass with a melting point of about 45° C. The product from the blubber oils of the bottlenose whale has a somewhat higher melting point. It is largely used in pharmacy as an unguent. It formerly was used in candle making and some soaps.

Spessartite (*Min.*) A manganese aluminium garnet, $6MnO, 3SiO_2 + 2Al_2O_3, 3SiO_2$; cubic. Commonly in dodecahedrons; deep brown red in colour. It imparts important cutting properties to some stones used for tool sharpening. From the Hartz, Sweden, Bavaria, and Piedmont.

Spewing (*Build., etc.*) When gravel, broken stones, etc., have been laid on a soft, wet surface (*e.g.* clay or mud), a quantity of mud is often forced out between the interstices. This is termed SPEWING. It is avoided by first forming a layer of coarse broken stone or "hard core" on the soft surface, and laying the gravel on this.

—— (*Leather Manufac.*) An exudation of oil from curried leather consisting of fatty matters which have failed to combine with the skin fibres, possibly on account of oxidation.

Sp. Gr. The contraction for SPECIFIC GRAVITY (*q.v.*)

Sphalerite (*Min.*) *See* ZINC BLENDE.

Sphene (*Min.*) Calcium titano-silicate, $CaO.TiO_2SiO_2$. Calcium oxide = 24·2, titanic acid = 43·2, silica = 32·5 per cent. Monosymmetric; usually brown and lustrous; rarely green. It is a common constituent of metamorphic rocks. It is found in the Criffel granite; in Argyllshire in schists; in Devonshire, France, Norway, etc.

Sphere. A surface of which all points are equidistant from a given point, termed the CENTRE of the sphere. A DIAMETER is a straight line passing through the centre and terminated at each end by the surface; a RADIUS, a straight line from the centre to the surface. Every plane section of a sphere is a circle; if the plane pass through the centre of the sphere, the circle is termed a GREAT CIRCLE; any plane not passing through the centre produces a SMALL CIRCLE. The AXIS of a great or small circle is the diameter of the sphere at right angles to the circle; the POLES of the circle are the ends of this diameter. Great circles passing through the poles are termed SECONDARIES to the circle. The part of the surface lying between three arcs of great circles is termed a SPHERICAL TRIANGLE. The area of a sphere of radius r is $4\pi r^2$; the volume is $\frac{4}{3}\pi r^3$.

Spherical Aberration (*Phys.*) A pencil of parallel rays after reflection from a curved mirror, or refraction through a lens, does not in general converge to (or diverge from) a single point. (*See* FOCUS, *etc.*) This departure from the elementary law is termed SPHERICAL ABERRATION.

Spherical Candle Power (*Light*). The average of the values of the candle power of a source of light, measured in all directions, *i.e.* at every point on the surface of a sphere surrounding the source. It is equal to the candle power which a theoretical point source, emitting light with uniform intensity in all directions, must possess in order that it may

emit the same total quantity of light as the source under consideration.

Spherical Excess (*Surveying*). Denotes the error due to the curvature of the earth's surface in a survey of great extent.

Spherical Triangle (*Geom.*) A part of a spherical surface intercepted between three arcs of great circles which intersect each other.

Spheroidal State (*Phys.*) If a small quantity of liquid be placed on a surface heated to a temperature considerably above the boiling point of the liquid it will collect into globules which roll about without boiling. A layer of vapour is formed between the drop and the hot surface.

Spheroidal Structure (*Geol.*) Artificial glass, if permitted to cool very slowly, tends to lose its transparency at many points throughout the mass; and when the glass has finally cooled, these semi-opaque areas are seen to be spheroidal in form, and to be made up of needlelike particles radiating from the centre of the spheroid. Recent investigations have proved that these needles consist of wollastonite, a silicate of lime. Many natural glasses and slags of eruptive origin show a similar structure, and to these the above name is given.

Spherometer (*Phys., etc.*) An instrument for measuring the radius of a spherical surface. It has three equidistant fixed pointed feet, which rest on the surface; in the centre is a screw with a pointed end, which can be raised or lowered by turning a graduated head fixed to the screw. The instrument is first placed on a plane surface, and the screw turned until its point exactly touches the surface: it is then transferred to the spherical surface and the screw raised (or lowered) until it again touches. If a be the distance through which the screw has been raised or lowered, and l the distance between the fixed points, the radius of the surface R is given by the formula

$$R = \frac{l^2}{6a} + \frac{a}{2}$$

Spherulitic Structure (*Geol.*) The term applied to the ball-shaped masses which many eruptive rocks, especially those of basic composition, are apt to assume after they have been exposed for some time to the weather.

Sphyrelaton (*Archæol.*) The name given to ancient hammered metal work.

Spider (*Elect. Eng.*) The part of an armature by which the core discs are supported and connected to the shaft; usually furnished with arms corresponding to the spokes of a wheel.

Spider Wheel (*Eng.*) Any wheel with very light radial arms.

Spiegel *or* **Spiegeleisen** (*Met.*) A pig iron or white cast iron containing 3·5 to 6 per cent. of carbon, and from 2 to 12 per cent. of manganese. Its fracture often presents well developed crystalline planes, hence the name. If the manganese is much in excess of the latter amount, the name FERRO-MANGANESE (*q.v.*) is given to the alloy. Spiegel is much used in steel manufacture as a convenient means of adding additional carbon, etc., to iron which has been almost entirely decarburised, as in the Bessemer, the Siemens, or the Siemens-Martin process (*q.v.*)

Spigot. (1) The end of a pipe that fits into the faucet or socket of another pipe. (2) A pin or small plug used to stop a faucet (*q.v.*) or a hole in a cask.

Spike (*Eng.*) (1) A large nail. (2) The fastening, resembling a nail, used to fix railway chairs (*q.v.*) to the sleepers.

Spile (*Carp. and Join.*) A rod of wood provided with a notch in the side, in which a pencil is held; it is used in marking the contour of an irregular surface or edge to which another piece of wood has to be fitted. The end or point of the spile is applied to the surface at a suitable point, and a mark made by the pencil on a board held in a convenient position; this process is repeated at a series of points along the irregular surface until a sufficient number of marks have been made on the board to enable the true contour of the given surface to be drawn.

Spiling (*Carp.*) The method of scribing with a SPILE (*q.v.*)

Spills (*Met.*) Openings or crevices found in inferior wrought iron bars.

Spinæ (*Music*). The name given to the jacks or plectra of the spinet.

Spindle (*Eng.*) A small axle or shaft.

—— (*Textile Manufac.*) (1) A common term for anything which rotates for the purpose of winding thread into coils, on to bobbins, or on a bare spindle. (2) An iron rod on which a tube or bobbin holding the spun yarn is placed.

Spindles (*Met.*) *See* BREAKING PIECES.

Spindle Tree (*Botany*). *See* EUONYMUS.

Spindle Valve (*Eng.*) A valve whose motion is guided by a rod fixed to the movable portion and running through bearings.

Spinel (*Min.*) Magnesium aluminium oxide, $MgO.Al_2O_3$. The chief mineralogical varieties are: (1) Ordinary, (2) Ruby Spinel, (3) Ceylonite, (4) Chlorospinel, (5) Picotite. Varieties named from colour are: Red, Spinel Ruby; Rose, Balas Ruby; Black, Pleonaste; Orange, Red Rubicelle; Violet, Almandine Ruby. Spinel crystallises in the cubic system, usually in octahedra. It is distinguished from the true or Oriental ruby by its inferior hardness, different crystalline form, and slightly inferior density; from garnet by its infusibility; from zircon by its lesser density. It is largely used as a gem. *See* PRECIOUS STONES. It is found in metamorphic rocks in Ceylon, Pegu, Siam, New Jersey, etc., and elsewhere in rocks of eruptive origin.

Spinel Ruby (*Min.*) A variety of SPINEL (*q.v.*)

Spinet (*Music*). A keyed instrument, varying in shape, played by means of jacks, and having one string to each note. The strings ran from left to right of the performer. In the Victoria and Albert Museum, South Kensington, may be seen various specimens of the spinet, as well as a clavicymbalo, an instrument with four strings to each note, two giving 8 ft. tone and the others 4 and 16 ft. tone respectively, which were also played by jacks. The spinet was in use in the sixteenth, seventeenth, and eighteenth centuries. *See also* MUSICAL INSTRUMENTS, p. 429, and VIRGINAL.

Spinning. *See* COTTON, LINEN, SILK, WOOL, MULE, RING FRAME, ROVE, SLIVER, SLUBBING, SPINNING JENNY, YARN, *etc.*

Spinning Jenny (*Cotton Manufac.*) The first machine by which the modern system of mechanically spinning cotton into yarns was effected. Invented by Hargreaves of Blackburn (Lancashire). In this machine the necessary degree of fineness

was imparted to the rovings by drawing them through "cloves," or clasp rods, instead of, as at the present time, by passing between rollers. It formed the nucleus of the subsequent inventions of Arkwright's water frame and Crompton's mills.

Spinning Metal (*Eng.*) The formation of circular objects from thin sheet metal in a lathe. The sheet metal is placed in front of a mould attached to the mandrel, and pressed into the mould as it revolves by a suitable tool. The latter resembles a burnishing tool, and has a rounded end, which is kept lubricated. Pewter and similar alloys can be *spun* very easily, but brass and copper can be treated in the same way if they are well annealed. Such objects as plates, cups and bowls, etc., are thus produced.

Spiral. A spiral is a plane curve, generated by a point which travels along a line while the latter rotates round a fixed point termed the POLE; the velocity of the moving point along the line (or RADIUS VECTOR) is related to the angular velocity of the latter by a definite law which determines the form of the spiral. Let r be the distance of the generating point from the pole, and θ the angle through which the radius vector has turned from some given position; then

for the SPIRAL OF ARCHIMEDES, $r = a\theta$;

for the LOGARITHMIC SPIRAL, $r = a\epsilon^{b\theta}$;

for the HYPERBOLIC SPIRAL, $r\theta = a$.

Spiral Gear (*Eng.*) Worm wheels, helical gear wheels, etc. (*q.v.*)

Spiral Nebulæ (*Astron.*) Nebulæ take various forms, among which a great number are spiral shaped. The nebula of Andromeda is the easiest to observe.

Spiral Spring. Strictly speaking, a spring coiled in one plane, such as a watch spring. But the term is also commonly applied to a HELICAL SPRING (*q.v.*)

Spire (*Architect.*) The tapering part of a steeple rising above the tower, forming a roof of very acute pitch. It is one of the characteristic features of Gothic architecture. *See* FLÈCHE *and* BROACH.

Spirillum (*Biol.*) Bacteria having the form of long unjointed threads, coiled into a spiral form.

Spirit. A term which includes METHYLATED SPIRIT, RECTIFIED SPIRIT, *and* SPIRITS OF WINE (*q.v.*)

Spirit Fresco. *See* PAINTING (METHODS).

Spiriting Off. *See* FRENCH POLISHING.

Spirit Level. A device for detecting deviations from a horizontal position. It consists essentially of a glass tube (or other suitable receptacle) containing spirit in which is a bubble of air; this bubble always moves towards the highest point in the tube, so that if one end of the tube be higher than the other the bubble moves to that end. The glass tube is attached to a suitable base, usually of wood.

Spirit, Motor. A mixture of the lighter petroleum hydrocarbons, having a specific gravity of 0·68 to 0·7. The test of gravity alone is an insufficient guide to the value of a spirit as a motor fuel. The chief characteristics to be noted are: (1) total range of vaporisation, (2) percentage volatile at 212° F. In (1) there is a guide to homogeneity, and a good spirit should have a range of 65° to 77° between the temperature at which it first gives vapour and the temperature at which it is wholly vaporised. In the case of (2) as much as 90 to 95 per cent. should be volatile at the temperature of boiling water (212° F.) Some spirits are as low as 81 per cent. No. 2 is an index to easy "starting up." This is *data* which can be easily supplied by any motor spirit maker, and will be found most instructive to the motor builder in determining the fuel best suited to his engine, as well as to the motorist in comparing the relative cost and efficiency of motor spirits.

Spirito, Con; Spiritoso (*Music*). With spirit; in a lively manner.

Spirit of Hartshorn (*Chem.*) (1) A solution of carbonate of ammonia distilled from Hartshorn. (2) At present it is generally the ordinary ammonia of the British Pharmacopeia (10 per cent. by weight NH_3).

Spirit Oil. A pale yellow light distillate that is sometimes obtained in the distillation of Yorkshire grease before the "first distilled grease" begins to run. It darkens on exposure to the air, and much resembles the distillate from bone tar. It boils at 150° C.

Spirits of Salts. A trade name for HYDROCHLORIC ACID (*q.v.*)

Spirit Varnish. *See* VARNISHES *and* FRENCH POLISHING.

Spitz-flöte (*Music*). A conical wooden organ pipe of thin, reedy tone. It is generally of 4 ft. tone, though it may also be of 8 or 2 ft. tone. Its name means "pointed flute."

Splashing (*Plumb.*) Placing melted solder on a joint that is to be wiped (*q.v.*) by throwing or splashing it from a ladle.

Splay (*Build.*) A sloping surface, larger than a chamfer; a surface making an oblique angle with another surface. To "splay" is to form such a surface on any object or part of a building.

Splayed (*Build.*) *See* SPLAY.

Spleen (*Zool.*) A spongy glandular organ forming one of the "ductless glands" found in vertebrates. It lies in the upper part of the abdomen, near the stomach, and has functions concerned with the blood corpuscles.

Splice. (1) A joint formed in timber by lapping the ends of two pieces together; sometimes used as synonymous with SCARF. (2) A joint in a rope, etc.

Spline. (1) A projecting ridge on a shaft, serving as a fixed key (*q.v.*) for a pulley, etc. (2) A thin lath or rod, usually of lancewood, used to aid the drawing of smooth curves through a number of given points.

Split (*Leather Manufac.*) A skin that has been split into two layers by a cutting machine. *Cf.* HAIR SPLIT *and* FLESH SPLIT.

—— (*Textile Manufac.*) *See* REED.

Split Bend (*Plumb.*) A bend in a pipe, made in two pieces.

Split Phase (*Elect. Eng.*) The division of an alternating current into two parts, differing in phase, is termed SPLITTING THE PHASE. If the current be divided into two branches in parallel with each other, one of these having a large resistance, the other a large self induction, the difference of phase will approach the maximum value, 90°. The device is commonly used in starting single phase motors. *See* MOTORS, ELECTRIC.

Split Pin. Usually made from a length of wire of hemispherical section, which is bent round until the flat sides are in contact, a small loop or head being formed at the bent end. The split end is passed through a hole in a rod or shaft, and the ends separated. The loop and the separated ends thus serve to retain some object in place.

Split Pulley (*Eng.*) A pulley made in two halves, which are placed in position on a shaft and then bolted together. By this means a pulley can be fixed on a shaft already in place without removing it from its bearings.

Split Ring (*Eng.*) A PISTON RING (*q.v.*)

Splitting (*Foundry*). Dividing a mould into two by means of a flat iron plate, termed a SPLITTING PLATE, in order to obtain a casting in two halves; the method is employed in casting split pulleys (*q.v.*)

—— (*Leather Manufac.*) The process of splitting leather into two or more layers parallel with the surface. *Cf.* CHAMOIS LEATHER.

Splitting Plate (*Foundry*). *See* SPLITTING.

Split Wheel (*Eng.*) Any wheel divided in two, as in the case of a SPLIT PULLEY (*q.v.*)

Spodumene (*Min.*) Aluminium lithium silicate, $Al_2O_3 . Li_2O . 4SiO_2$. Alumina = 29·4, lithia = 6·4, silica = 64·2 per cent. Monosymmetric. Grey or greenish, with very perfect cleavage parallel to the orthopinacoid. In the Peterhead granite, from co. Dublin, Sweden, Tyrol, the United States, etc.

Spoilage (*Print.*) The "waste" or spoiled sheets in printing.

Spoke Machine (*Eng., etc.*) A form of copying lathe used for making wooden spokes for wheels The piece of wood revolves in the lathe, and the tool moves backwards and forwards at right angles to the axis of rotation, being guided by an iron template of suitable form.

Spokes. The arms of a wheel.

Spokeshave (*Carp., etc.*) A tool consisting of a cutting iron of which the action is similar to that of a plane, but it is mounted in a stock or holder whose principal length is parallel to the cutting edge; the ends of the stock are formed into two handles by which the tool is moved backward and forward. Spokeshaves are chiefly used on work which possesses a considerable curvature, *e.g.* handrails, etc.

Sponge (*Met.*) A mass of iron from the puddling furnace not yet hammered into a homogeneous mass.

—— (*Zool.*) Sponges form a lowly division of the animal kingdom, coming just above the Protozoa, or simplest animals. They are marine animals, sedentary and passive like plants, with which they were once classified. They possess a skeleton formed of calcareous or siliceous spicules, or of fibres of a material termed SPONGIN, which resembles silk in its chemical composition. Both spicules and spongin fibres may occur in the skeleton. The sponge of commerce is the dried skeleton.

Sponge Bed (*Geol.*) In the Cretaceous Rocks, fossil sponges occur in abundance, and in some cases are sufficiently numerous to form beds of rock, which are termed Sponge Beds.

Sponge Cloth (*Eng.*) A cloth of loose texture used in place of cotton waste for wiping oil off machinery.

Spontaneous Combustion. Combustion produced without the application of heat from an external source.

Spoon Bit (*Carp.*) A form of wood boring bit somewhat resembling a small gouge, but having its cutting edge curved in profile.

Spoon Gouge. A gouge (*q.v.*) with a bent blade for cutting out cavities with curved internal surfaces.

Spot Cotton (*Cotton Trade*). Actual cotton bought for cash through a broker for immediate use at mill. *Cf.* FUTURES COTTON.

Spotting Motion (*Textile Manufac.*) A motion on the twisting frame for developing spots, at intervals, on the surface of twist yarns.

Spouts (*Meteorol.*) Cloud-like or fog-like phenomena of a slender and more or less tapering form formed in the air under certain atmospheric conditions. The more common form is a waterspout (*q.v.*)

Spray (*Foundry*). A small GATE or RUNNER (*q.v.*)

Spray Carburetter (*Motor Cars, etc.*) A spray carburetter consists of a small chamber, into which the liquid fuel (oil, spirit, etc.) used for driving a petrol or similar motor is converted into vapour and mixed with air to form an explosive mixture. The liquid enters the chamber through a small orifice which communicates by means of a tube of small bore with the tank in which the oil or spirit is stored; the supply of liquid is usually governed by a needle-valve actuated by a hollow metal float, which closes the opening when the liquid enters too rapidly. The stream of liquid being very fine quickly breaks up into fine drops, which rapidly vaporise in the chamber; the vapour mingles with air, and is drawn into the cylinder of the engine. *See* PETROL ENGINE. MOTOR CARS, CYCLES, *etc.*

Spray Tuyère (*Met., etc.*) A TUYÈRE (*q.v.*) cooled by water impinging on its surface in the form of very fine jets or spray.

Spreading Power of Pigments. *See* COVERING POWER.

Sprengel Pump. *See* AIR PUMPS.

Sprig. A brad or nail cut out of sheet metal.

Sprigging (*Carp., etc.*) To fasten with sprigs.

—— (*Foundry*). Supporting small and weak portions of a mould by means of thin sprigs or brads which are driven into the sand.

Spring (*Eng., etc.*) A piece of elastic material (tempered steel, hard brass, wood, rubber, etc.), generally in the form of a thin rod or ribbon, employed to exert a force in a definite direction when bent or otherwise distorted. This force may be required to actuate mechanism as in clockwork, to diminish the effect of sudden shocks, as in vehicles, or to exert some controlling effect on a moving part in certain mechanism. *See also* HELICAL *and* SPIRAL SPRINGS.

—— *or* **Springing** (*Architect.*) The point where the curved portion of an arch meets the abutments or piers. *See* ARCH.

Spring Balance. A device consisting essentially of a helical spring, whose extension is proportional to the weight or other force applied to it; the amount of this force is ascertained by reading off the extension of the spring on a properly divided scale which is attached to it.

Spring Bows. Small compasses whose legs are connected by a flat steel ribbon forming a spring, instead of by means of a hinge. The distance apart of the points can be regulated by means of a screw and nut.

Spring Chuck (*Eng.*) A chuck (*q.v.*) in the form of a hollow cylinder or cup, with several fine slits cut parallel to the axis. An object which is placed in a chuck of suitable size can be held fast by the pressure of the sides of the chuck, aided, if necessary, by a ring driven on to the outside of the chuck (which is turned to a slight taper). These chucks are only suitable for light work, but are very convenient when a considerable number of objects the same size are being turned up.

Spring Dividers. DIVIDERS (*q.v.*) with a spring joint similar to that of SPRING BOWS (*q.v.*)

Springer (*Build., etc.*) The stone abutment at the springing of an arch. *See* ARCH.

Springing Line. *See* ARCH.

Spring Jack. An interceptor used in curtain manufacture, so formed that it has sufficient elasticity to place itself in action upon the release of a string.

Spring Pawl (*Eng.*) A pawl or catch of a ratchet wheel which is caused to fall into its place by means of a spring.

Spring Ponty (*Glass Manufac.*) A tube of iron having a flat circular plate attached at one end. A light rod of iron running down the centre of the tube has a plate at its end in the form of a horseshoe. By means of a spring, the plate attached to the tube is made to press against the horseshoe plate. The foot of a wineglass is placed between these, and held in position by the spring. This allows the workman to finish the article the same as if it were *stuck* to the ordinary ponty.

Spring Pulley (*Eng.*) A pulley made of wrought iron or steel, divided by a cut passing through the boss and one side of the rim. It can be sprung open sufficiently far to enable it to be passed over a shaft, thus serving the same purpose as a true SPLIT PULLEY (*q.v.*)

Spring Ring (*Eng.*) A PISTON RING (*q.v.*)

Spring Safety Valve (*Eng.*) A SAFETY VALVE (*q.v.*) which is closed by a spring instead of a weight. The force acting on the valve is independent of the position or motion of the valve, and therefore a spring safety valve is suitable for locomotive or marine boilers.

Spring Tides (*Astron.*) *See* TIDES.

Spring Tool (*Eng.*) A metal turning tool which has a bend in its shank near the point. This enables the tool to yield or spring to a slight extent. It is used for taking a very light finishing cut on a piece of work which has been turned to very nearly its exact size.

Spring Water. *See* SPRINGS; WATER; *and under* SANITATION.

Springs. The overflow of the ground water. The rain, falling on a permeable stratum, percolates downwards until it reaches an impermeable stratum, and it is this underground store which crops up and forms springs. Various conditions determine the amount of rain which penetrates the ground, namely, the nature of the soil, the configuration of the land, the temperature and the movement of the air. Clay is almost impermeable, whilst gravel or a loose sandy soil absorbs about 96 per cent., limestone about 20 per cent., and chalk about 42 per cent. With an increase of temperature evaporation is rapid, and less water penetrates the surface. In a flat district evaporation is 50 per cent. less than in an undulating one. When springs flow from artificial gravel beds they are termed "land springs"; these are shallow, and their flow is not constant. "Main springs" are found in deeper strata, and yield a regular supply. Springs sometimes hold in solution some of the mineral constituents of the rocks through which they pass. In many of these the mineral matter is so excessive as to render the water unfit for ordinary drinking purposes, though they are of value medicinally. The temperature of such springs is often high.

Springs (*Geol.*) Springs may be divided into two classes in accordance with their origin: (1) Normal springs, sufficiently described above; and (2) THERMAL SPRINGS, which are due to the uprise of heated waters from a subterranean source. These latter bring up various substances in solution, and eventually deposit them at higher levels at the points where the temperatures of the adjoining rock are lower than those of the initial temperature of the spring.

Sprocket or **Sprocket Wheel** (*Eng., etc.*) A toothed wheel driven by a chain. In cycles the term is usually reserved for the wheel on the driving axle of the machine. *See* CYCLES.

Sproket Piece (*Carp. and Join.*) A tilting fillet fixed on the lower ends of roof rafters.

Spruce. *See* WOODS.

Sprue (*Foundry*). A channel or runner by which molten metal enters a mould. *See* GATE.

Spun Metal. *See* SPINNING METAL.

Spun Silk. *See* SILK.

Spun Yarn (*Eng.*) In engineering this term is applied chiefly to loosely spun hemp rope, which is used as packing for stuffing-boxes and joints in steam pipes.

Spur (*Print.*) *See* POINTS.

Spurious Disk (*Astron.*) Owing to light of all wave lengths not being brought to a focus at one point, the image (say of a star formed by a lens) is a disc, surrounded by a series of interference rings.

Spur Wheel (*Eng.*) A toothed wheel of the ordinary form, *i.e.* with the teeth on the outside of the rim.

Squabble (*Typog.*) To disturb the arrangement of lines of type so as to render it unfit for printing; *i.e.* to "pie" the matter.

Squall (*Meteorol.*) A local rush of air which restores normal conditions when the air has been disturbed by local causes. High wind and heavy downpours generally accompany it.

Square. A geometrical plane figure having four equal sides and four right angles.

—— (*Build., etc.*) One hundred square feet of boarding, slating, etc.

—— (*Eng., Carp., etc.*) A tool used for drawing, setting out, or testing right angles. It has a stock of wood or metal and a flat thin blade, usually of

steel, set at right angles to one edge of the stock. The squares used by workmen are usually in the form of a letter L; those used by draughtsmen are in the form of a letter T, and are therefore known as T-SQUARES.

Square and Flat (*Carp.*) Framing without moulding, and with a flat panel.

Square Centre (*Eng.*) A piece of steel placed in the back head or poppet of a lathe in place of the ordinary centre, in order to cut a conical hole in a piece of work placed in the lathe; its point is made in the form of a square-based pyramid, instead of being conical. When a hole of sufficient depth has been cut, the square centre is removed and an ordinary centre is substituted.

Squared Paper. Paper ruled with two sets of lines, often $\frac{1}{10}$th in., or 1 millimetre, apart; used for plotting curves from a series of numbers obtained by calculation or experiment.

Squared Rubble (*Build.*) Stone walling in which the stones are squared on the face.

Square Nosed Tool (*Eng.*) A metal turning tool with a straight cutting edge, at right angles to the axis of the tool; it is used for finishing work which has been roughed out by a round nosed or a pointed tool; the ridges left by the latter are removed by the straight cutting edge.

Square Packing (*Eng.*) Rope or gasket plaited into a square section for filling joints or stuffing-boxes.

Square Threaded Screw (*Eng.*) *See* SCREW.

Squaring Up (*Carp.*, *Eng.*, *etc.*) The production of sides or faces on a piece of work accurately at right angles to one another.

Squeezer (*Met.*) A machine by which a ball of puddled iron is pressed into a homogeneous mass, ready for the rolling mills.

Squills (*Botany*). The sliced and dried bulb of *Urginea scilla* (order, *Liliaceæ*) forms the drug of this name.

Squinch (*Architect.*) The arches or series of projecting courses carrying four of the sides of an octagonal spire across the angles of a square tower.

Squint (*Architect.*) *See* HAGIOSCOPE.

—— (*Build.*) A term loosely applied to an object cut at an obtuse or acute angle.

Squint Brick (*Build.*) A brick cut to an acute or obtuse angle.

Squirrel Cage Rotor (*Elect. Eng.*) A ROTOR or revolving portion of an alternating current motor, built up of parallel bars of copper, joined together at their ends by a conducting rim or disc.

Squirting (*Chem. Tech.*) *See* PLOTTING.

Sr (*Chem.*) The symbol for Strontium (*q.v.*)

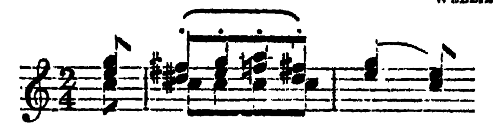
Stabbing (*Bind.*) A method of attaching the various sections or sheets of a volume or pamphlet together. The sections are placed in a pile, pierced near their back edge, and then secured by wire or thread passed through the holes. *See* SEWING *and* STITCHING.

Stable Equilibrium (*Phys.*, *Mech.*) *See* EQUILIBRIUM, STABLE.

Staccatissimo (*Music*). As separated as possible. *Cf.* STACCATO.

Staccato (*Music*) Detached, separated. Staccato is the opposite to *legato*. There are three degrees of staccato, shown respectively by dots with a slur, by dots, by dashes. The following brief examples show these, and an approximate idea of their performance is given beneath each:

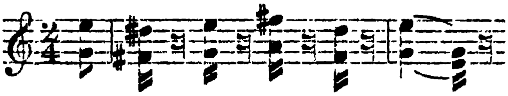
Ex. 1.—MEZZO STACCATO (as written). WEBER.



MEZZO STACCATO (as played), three-quarters note, one-quarter rest.

Ex. 2.—STACCATO (as written). WEBER.

STACCATO (as played), half note, half rest.



Ex. 3.—STACCATISSIMO (as written). MOZART.

STACCATISSIMO (as played), one-quarter note, three-quarters rest.

Stack. In engineering, a single tall chimney. Builders usually apply the term only to a number of chimneys or flues grouped together.

Stadia (*Surveying*). The staff used in conjunction with the tacheometer (*q.v.*) or similar instruments for the indirect measurement of distances.

Stadium (*Archæol.*) (1) A course on which foot races took place in Greece; the most celebrated were at Olympia and Athens. (2) The distance between the terminal pillars of the stadium, *viz.* 600 ft., equal to 625 Roman feet.

Staff (*Music*). *See* STAVE.

—— (*Watches*). The small spindle or arbor on which the balance (*q.v.*) is mounted. The arbor of the pallets of a lever watch is also called a staff. *See* ARBOR.

Staff Bead. *See* ANGLE BEAD.

Stafford Blues. *See* BRICKS.

Stage. (1) A flat surface forming a support; the term has many applications, *e.g.* a Landing Stage, the Stage of a theatre, etc. (2) The part of a microscope

(*q.v.*) or of an optical lantern which supports the slide or other object to be viewed. (3) A definite point in a series of operations, or one operation of a series.

Stage (*Geol.*) A name now applied to one of the minor groups of beds, which are themselves composed of several strata. Stages unite to form a Series, Series to form a System, and Systems to form a Group.

Stage Micrometer. *See* EYEPIECE MICROMETER.

Stage Pass (*Textiles*). *See* ENTERING.

Staggering (*Eng., Elect. Eng., etc.*) An arrangement of a number of separate objects, *e.g.* rivets, so that they are not exactly opposite to, or in line with, each other.

Stag's Head (*Her.*) The antlers of a stag in heraldry are called "attires"; the branches, "tynes."

Stain (*Dec.*) Colouring matter dissolved in oil, spirit, or water, and sufficiently transparent to show the grain of the wood through.

Stainers (*Dec.*) The popular term among painters for all pigments which are mixed with white lead, zinc white, etc., for painting purposes. *See* PAINT MIXING.

Staining (*Leather Manufac.*) Brushing over the surface of leather with a strong solution of a dye-stuff; commonly called BRUSH DYEING.

Staircase (*Build.*) Staircases are built of wood, stone, or iron, the former being employed in most private buildings. A wooden staircase consists of a succession of steps, each formed by two boards, one forming the TREAD or horizontal surface on which the foot rests, the other being placed vertically so as to fill in the space between two successive treads: this is termed a RISER. The edge of a tread usually projects beyond the riser, and is rounded off or moulded, forming a NOSING. If the nosing is carried round the end of a step, so as to cover the exposed end of the tread, it is termed a RETURNED NOSING. If a small scotia (*q.v.*) is fixed to the riser under the nosing, the latter is termed a BOTTLE-NOSE. A step with a rounded end is termed a BULL-NOSE STEP: this is often used for the lowest step of a flight. If this step has the end formed into a volute, corresponding to the form of the wreath on the end of the handrail, it is termed a CURTAIL STEP. The width of a tread is termed the GOING, the expression "going of a flight" being the horizontal distance over which the whole flight of steps extends. The ordinary steps, whose width is uniform, are termed FLIERS, those of triangular or tapering form, which occur where the stairs turn or "wind," being termed WINDERS. A winder which occurs right in the angle of a staircase is usually kite-shaped, and is termed a KITE WINDER. The ends of the treads and risers are supported by boards termed STRINGS, running the whole length of each flight. The string next to the wall is termed a WALL STRING, the other or outer one a WELL STRING, as it lies next to the WELL, or central space of the staircase, which is seen when looking down from an upper landing. If the upper edge of the string forms one continuous line, the term CLOSE STRING is applied to it; a CUT STRING is one which is cut out into right-angled notches following the profile of each step. The ends of each step in a cut string may be concealed by ornamental brackets fixed to the string, forming a BRACKETED STRING, or the ends of the risers may be mitred to the vertical edges of the notches in the string, thus forming what is termed a MITRED STRING, or CUT AND MITRED STRING. If the strings form a continuous line where the staircase bends round, they are said to be WREATHED, the same term being applied to the handrail. The latter is a moulded rail on which the hand rests; it is supported by vertical pillars, termed BALUSTERS, rising from each step; the large column at the end of a flight, to which the ends of a handrail are attached, is a NEWEL. Stairs are sometimes provided with extra support in the form of roughly made strings placed under the steps: these are termed ROUGH STRINGS or ROUGH CARRIAGES. The resting places between the flights are termed LANDINGS, a HALF SPACE LANDING being one which extends the whole width of the staircase, a QUARTER SPACE LANDING extending the width of one flight.

Stake. (1) A general term for a bar with a pointed end. (2) In the foundry a spike driven into the floor for holding a moulding box in position. (3) A form of anvil used by sheet metal workers; it generally has a small face or plain surface, and long projecting points or beak irons.

Staking (*Leather Manufac.*) Drawing leather, in a moist condition, vigorously over a bluntish blade fixed on an upright post. This stretches and softens the leather, and prevents the fibres from sticking together while drying.

Staking On (*Eng.*) Fixing a wheel on a shaft by means of several keys; the wheel is not accurately bored out to fit the shaft, but has an opening larger than the diameter of the shaft, and correct centring or adjustment is obtained by the keys alone.

Stalactites (*Geol.*) Pendent masses of some rock-forming mineral, rudely circular in cross section, which have been deposited on the inner side of the roof of a cavity by the slow evaporation of water holding the substance of that mineral in solution. The best known examples are those of carbonate of lime, such as may be seen depending from the soffit of a railway arch, and which are due to the solution of some of the carbonate of lime in the mortar, and its redeposition at a lower level under the joint influence of surface tension and gravitation. Nearly all limestone caverns contain stalactites of carbonate of lime. Stalactites may be formed by almost any mineral, *e.g.* hæmatite, chalcedony, malachite, etc.

Stalagmite (*Geol.*) Deposits found in the same manner as stalactites; but left upon the floor of the chamber instead of being pendent from the roof.

Stall Board (*Carp. and Join.*) The boarding inside a shop window on which the goods are displayed.

Stalls (*Architect.*) The fixed and partially enclosed seats in the chancel of a church, used by the clergy and others assisting in the services.

Stamnos (*Archæol.*) A two-handled earthenware Greek jar with very short neck, used for holding liquids; often decorated with red figures.

Stamp (*Met.*) (1) Specifically that portion of the machine of a stamp mill that delivers the blow by which ore is reduced to a suitable size for further treatment in the processes of separating the valuable constituents. (2) A STAMPING MACHINE (*q.v.*) (3) A STAMP MILL (*q.v.*) *See also* SLIME *and* STAMPS.

Stamping (*Textile Manufac.*) The operation of punching the cards for the harness loom according to a given design.

Stamping Machine, Stamping Press. (1) A machine used for forming metal articles, generally in the rough. (2) A machine, generally worked by power, for forming hollow metal utensils. The shaping is effected, not by a blow, but by a continuous pressure brought to bear on the dies.

Stamping Press (*Bind.*) *See* BLOCKING PRESS.

Stampings (*Eng., etc.*) Metal objects produced by means of dies actuated by a press or stamping machine. Some metals may be used in the cold; others require heating. Among the latter is wrought iron, stampings of which are frequently made, thereby saving much labour in the forge.

Stamp Mill (*Met.*) A machine or set of machines for crushing ore by means of vertical blows.

Stamps (*Met.*) Another name for NOBLINS. Also the rough bars of about 28 lb. each obtained by nicking or partially cutting through a bloom or noblin. The stamps are broken to judge the grain of the metal before preparing a "pile" in the production of malleable and sheet iron.

Stanchion. A vertical bar or post serving as a support; *e.g.* an iron column (which may be built into a wall) carrying the end of a girder.

Stancliffe *and* **Darley Dale Stone.** *See* BUILDING STONES.

Standard. A fixed measure, weight, value, or quality, established by law or sanctioned by usage and general consent, which serves as a definite unit of comparison. A flag or banner serving as the emblem of a government or society; an ensign.

—— (*Build.*) (1) A vertical support (*cf.* STANDARD, *Eng.*) (2) A vertical pole of a scaffold.

—— (*Eng.*) A term applied in a very wide sense to various supports, upright framing, etc., forming part of a machine, bridge, pier, or other structure.

Standard Candle. A sperm candle, consuming 120 grains (about 7·8 grams) of wax per hour, is taken as a standard of illumination, and the amount of light it affords, termed ONE CANDLE POWER, is used in determining the illuminating power of other sources of light. The two lights are compared by some form of Photometer (*q.v.*)

Standard Diets (*Hygiene*). *See* FOODS.

Standard Gold (*Met.*) *See* CARAT.

Standardisation. (1) The comparison of any measuring or recording instrument with another of greater accuracy, or with one whose errors are exactly known. (2) In engineering, etc., the production of component parts of machines or structures in accordance with certain sets of measurements previously agreed upon.

Standard Rule (*Eng., etc.*) A rule divided exactly into inches, etc., as distinguished from a CONTRACTION RULE (*q.v.*)

Standard Solutions. For the purposes of volumetric analysis, and for a great number of different purposes in chemistry and other scientific and technical work, it is necessary to have solutions of various substances of accurately known strength; this strength is generally chosen with reference to some convenient standard depending on the precise use for which the solution is required. For example, solutions of an acid and of an alkali may be so made up that equal volumes exactly neutralise each other; in this case the quantities (by weight) of the acid and alkali contained in equal volumes of the solution are proportional to their respective reacting weights. A solution containing 35·5 grams of HCl will neutralise another containing 40 grams of NaOH. If the two amounts are each contained in 1 litre of solution, the latter is termed a NORMAL SOLUTION. A DECI-NORMAL SOLUTION is one-tenth of this strength, and so on for other strengths. Standard solutions may, of course, be made of any other strength (subject to the solubility of the given substance); *e.g.* a solution of silver nitrate may be made so that 1 c.c. will exactly correspond to 1 milligram of common salt or 1 milligram of chlorine.

Standard Time (*Astron.*) The time at every meridian fifteen degrees apart, commencing with the Greenwich meridian.

Standard Wire Gauge. *See* WIRE GAUGES.

Stand Pipe. (1) A large vertical pipe at a water source, into which water is forced in order to obtain sufficient pressure to carry it to a distance. (2) A small vertical pipe having direct connection with a water main. (3) A pipe sufficiently high to force water into a boiler against steam pressure.

Stanford's Patent Drain Joint (*San.*) is one in which the spigot and socket ends of each pipe are provided with a mould of smooth plastic material, causing them to fit accurately into each other. By greasing the prepared ends with rosin and melted tallow a perfect joint is formed.

Stanhope Press. *See* TYPOGRAPHY.

Stannates (*Chem.*) *See* TIN COMPOUNDS.

Stannic, Stannous, Stannum (*Chem.*) Stannum is the Latin name for tin; from it the chemical symbol for tin, Sn, is derived. Stannic is the prefix applied to tetravalent tin compounds. Stannous is the prefix applied to divalent tin compounds. *See* TIN.

Stannine (*Min.*) A sulphide of tin, copper, and iron, $Cu_2S(Fe,Zn)S \cdot SnS_2$; tin = 27, copper = 30, iron = 13, sulphur = 30 per cent. Also called Bell Metal Ore and Tin Pyrites. Cubic; colour greyish or bronze (hence Bell Metal Ore). If abundant it is used as an ore of tin. From several localities in Cornwall, from Zinnwald in Bohemia, etc.

Staple (*Build., etc.*) A piece of metal rod or wire pointed at the ends and bent into the shape of the letter U.

—— (*Textile Manufac.*) In the woollen and worsted trades a lock of wool. The quality and properties of wool are determined by the strength, length, and elasticity of the staple. For cotton, *see under* GRADING.

Starch (*Chem.*) $(C_{12}H_{20}O_{10})n$. A white powder, with or without lustre, according to its source. It is composed of small granules, having an organised structure, but varying greatly in this respect and also in size. Starch from various sources can be identified by a miscroscopic examination of the structure and size of the granule. For example, potato starch consists of circular or oval granules marked with rings, and a circular or stellar hilum, and a size from ·06 to ·1 mm. Starch ordinarily contains about 20 per cent. of water; if exposed to moist air, this amount may be much exceeded. It loses its water in a current of dry air at 100° to 105°. Does not melt when heated. Ordinary starch at 160° is converted into dextrine (British gum), which is soluble in water. Perfectly dried starch is not decompoble in

160°, but is decomposed at higher temperatures. Starch is insoluble in cold water, but when made into a paste with cold water and then heated the granules are gelatinised, the temperature at which this occurs varying with the kind of starch. If the cold paste (5 grams starch to 100 cc. water) be acted on by diastase for a few minutes only and then filtered, the solution contains starch, and an insoluble residue remains on the filter paper. The soluble part is called starch granulose, and the insoluble part starch cellulose, and it is the former which gives the dark blue colour with iodine. When the product of the action of diastase just referred to is quickly boiled to destroy the enzyme, filtered, and then concentrated, a white precipitate separates on cooling. The precipitate, allowed to stand a few days, and then well washed with water, gives SOLUBLE STARCH. This variety of starch is completely, but rather sparingly, soluble in water; it is a colloid; its solution is dextrorotatory, gives a blue colour with iodine, and does not reduce Fehling's solution. Boiling dilute acids convert starch first into soluble starch, then dextrine and maltose, and finally into dextrose. The action of nitric acid is very various. Fuming nitric acid (sp. gr. 1·5) gives an explosive nitrate or mixture of nitrates; a more dilute acid gives saccharic acid (*q.v.*); prolonged boiling with such an acid (sp. gr. 1·2) gives finally oxalic acid. With the diluted acid large quantities of nitric oxide and nitrogen peroxide are evolved. Iodine gives with starch a deep blue colour, which disappears on heating and reappears on cooling. What the blue compound is is quite unknown. Its production serves as a very delicate test for starch or iodine (it will detect ·000003 gram iodine). The action of diastase is very important. When starch paste is acted on by diastase at 60°, the starch paste becomes quite thin, and loses its power of giving a blue colour with iodine, acquiring instead the power of giving a brownish-red colour, and lastly it loses this power. The final products are maltose and dextrine. Potato starch gives more dextrine and less maltose than any other starch.

PREPARATION AND COMMERCIAL USES: Starch is used for a great variety of purposes: as a food in the form of the various cornflours, for infants' foods, and as arrowroot, etc.; for sizing paper and cloth, for the preparation of British gum and glucose, for laundry purposes. It is prepared in England chiefly from rice, in America from maize, in Germany and France from potatoes. Various processes are employed, but all are in the main mechanical. One process from rice is to digest the rice with very dilute caustic soda (about 1 in 350) solution for twenty-four hours, the liquor is drawn off, and the residue washed with water. The caustic soda removes the gluten which binds the starch granules in the rice. The residue is ground to powder, which is then sieved, and the fine product again treated with alkali as before, only it is frequently stirred during the twenty-four hours, and then left to stand seventy hours. The liquor is run away, the residue well stirred with twice as much water as soda solution, left an hour, and the turbid liquid, which now only contains the starch in suspension, run through fine silk sieves. The sieved liquor deposits the starch on standing, the water is drawn off, the starch drained, and dried in a current of air (six to eight weeks).

Starch (*Foods*). This exists in various farinacea in the form of microscopic granules, differing in form and size according to their origin. When acted upon by the saliva and pancreatic juice it becomes grape sugar; this, when taken up by the blood, is carried to the liver, where it becomes glycogen (*q.v.*), and from thence is supplied to the system. *See also* STARCH (*Chem.*)

Star Charts (*Astron.*) Maps on which the relative positions of stars are plotted. The positions are determined from observations with the transit circle, or more recently from photographs.

Star Connections (*Elect. Eng.*) An arrangement of the coils of a three phase motor, such that they have a common junction.

Star Magnitudes (*Astron.*) Stars were classified, long before the telescope was invented, according to their relative brilliancies. Those which appear largest and brightest are termed Stars of the First Magnitude; the next, stars of the Second Magnitude, and so on to the smallest stars visible to the naked eye, which are said to be of the Sixth Magnitude. The telescope has, of course, greatly increased the number, and the stars visible with a powerful instrument are classified down to the seventeenth or eighteenth magnitude, or even beyond. The number of stars in each magnitude is approximately given by Sir Robert Ball as follows:

1st magnitude	20
2nd ,,	65
3rd ,,	190
4th ,,	425
5th ,,	1,100
6th ,,	3,200
7th ,,	13,000
8th ,,	40,000
9th ,,	142,000

Star Moulding (*Architect.*) An enriched Norman moulding consisting of a series of sunk stars.

Starting Engine (*Eng.*) A subsidiary engine used on steamships to set the main engine in motion.

Starting Gear (*Eng.*) A term which comprises the whole of the mechanism called into action in order to start the motion of an engine or other machine.

Starting Valve (*Eng.*) The valve in a steam engine which admits steam from the boiler into the steam chest.

Star Wheel (*Eng.*) A ratchet wheel with large pointed teeth. It is used in various forms of ratchet feed, as, for example, on self acting lathes, when employed in surfacing (*q.v.*)

Stassfurt Deposits (*Chem.*) Large deposits of common salt and potassium and magnesium salts, which occur at Stassfurt, near Magdeburg. They have been formed by the evaporation of sea water. The potassium and magnesium compounds occur as double salts in fairly distinct layers in the order from above downwards:—

(1) Carnallite ($KCl.MgCl_2 6H_2O$), with kainite ($KCl.MgSO_4 3H_2O$), kieserite ($MgSO_4 H_2O$), schönite ($K_2SO_4 MgSO_4 6H_2O$), and sylvine (KCl), and a good deal of rock salt.

(2) Kieserite ($MgSO_4 H_2O$), with much rock salt and a fair amount of carnallite.

(3) Polyhalite ($2CaSO_4.MgSO_4.K_2SO_4 2H_2O$), along with a very large amount of rock salt.

(4) Rock salt ($NaCl$).

Besides these, certain amounts of borates and bromides occur. These deposits are the principal source of potassium compounds for the whole world. To give some idea of the scale on which they are worked,

it may be mentioned that in 1900 about 16,400 persons were engaged in working these salts at Stassfurt and the district around. In 1898 the production of potassium salts amounted to 2,200,000 metric tons (1 metric ton = 1,000 kilograms = ·9842 tons), of bromine 500 metric tons, and, in addition to these, large quantities of magnesium salts and boric acid. (*See* POTASSIUM *and* MAGNESIUM COMPOUNDS.) Extensive researches on the chemistry of the formation of these salts have been made with the aid of the Phase Rule, but these cannot be given here. *See* Findlay's "Phase Rule."

Stassfurtite (*Geol.*) A salt found in the Carnalite region. It is a massive variety of Boracite (*q.v.*)

State (*Engrav.*) When an engraved plate is nearing completion, proofs are taken at different stages to test its condition. These proofs are termed proofs of the first state, second state, and so on. When the engraving is completed the plate is referred to as being in the FINAL STATE. *See* PROOF.

Static Electricity *or* **Electrostatics.** The phenomena associated with charges of electricity at rest; the branch of the science of electricity dealing with these phenomena.

Static Fatigue (*Eng.*) Elastic fatigue (*q.v.*), produced by a continuous stress.

Static Friction. *See* FRICTION, STATIC.

Statics. The branch of theoretical mechanics dealing with forces at rest or in equilibrium.

Station (*Elect. Eng.*) A place at which electrical machinery or apparatus is maintained and operated; *e.g.* a CENTRAL STATION is the main building in which the engines and dynamos are placed for the supply of current to a lighting or power circuit. A TRANSFORMER STATION or SUBSTATION contains transformers (*q.v.*) for changing the voltage for distribution.

—— (*Eng., etc.*) (1) A building, etc., in which some form of central plant is located, *e.g.* a pumping station. (2) A stopping place on a railway for taking up or setting down passengers or goods, for shunting, making up trains, etc.

—— (*Mining*). A recess in a mine to provide a space in which cars can pass one another.

—— (*Survey, etc.*) A point from which measurements by distances or angles are made.

Stationary Engine (*Eng.*) An engine mounted on a fixed bedplate.

Stationary Points (*Astron.*) Points in a planet's apparent path where, as seen from the earth, the planet appears stationary or is moving in a direction either towards or away from the earth.

Stationary Waves. Periodic displacements occurring in a medium between successive points, termed the NODES, which remain permanently at rest. They are produced when two trains of equal and similar waves travel through the medium with equal velocities, but in opposite directions. The ordinary vibrations of a stretched string furnish an example.

Stator (*Elect. Eng.*) The stationary part of a polyphase motor carrying the windings through which the primary current flows. *Cf.* ROTOR, *and see* MOTORS, ELECTRIC.

Statuary Marble. *See* MARBLE, STATUARY.

Statue. A plastic work in marble, bronze, wood, or other material, representing a human or animal figure. *Cf.* STATUETTE.

Statue, Monumental. A recumbent figure on a slab covering a mediæval tomb.

Statuette. A statue (*q.v.*) the dimensions of which are generally less than half life size.

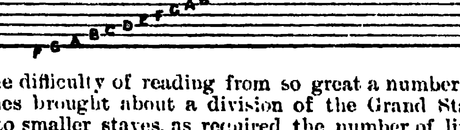
Staunch (*Eng.*) A joint in a boiler, etc., is said to be staunch when it is watertight.

Staurolite (*Min.*) An iron aluminium silicate, $H_2O.2FeO, 5Al_2O_3.4SiO_2$; silica = 29·3, alumina = 53·9, ferric oxide = 17·2 per cent. Orthorhombic, often in cruciform twins, whence the name Staurolite. Colour brown to black. It is found in some metamorphic rocks, as the slates of Devon and Cornwall. Also in Co. Dublin and Co. Wicklow; in Aberdeenshire; Switzerland, the United States, etc.

Stave (*Eng.*) A rod projecting from a large piece of iron. The iron is manipulated by means of the stave during forging operations.

—— *or* **Staff** (*Music*). A set of horizontal and parallel lines with equal spaces between. Upon the lines and between the spaces the notes and rests are placed. Each line and each space is called a degree, the degrees being reckoned from the bottom upwards. The present staves are derived from a stave of eleven lines called the Grand or Great Stave, the lines and spaces of which were as follows:

GRAND STAVE.



The difficulty of reading from so great a number of lines brought about a division of the Grand Stave into smaller staves, as required, the number of lines of which have varied from time to time. Old manuscript books often have staves of six lines, the lines of which correspond to the present Treble Stave (*see* below), with middle C line (the sixth line of the Grand Stave) added below. Plain song is still written on a stave of four lines. (*See* MODES.) The stave of five lines is now used for all kinds of music except Plain song. The splitting up of the Grand Stave into smaller staves required signs called clefs (*q.v.*) to indicate which set of lines had been taken from the eleven. These clefs appear to move in the different staves; but in reality this is not the case. The clef is stationary, but the lines chosen from the Grand Stave vary. The following show the different staves, and which lines of the Grand Stave were selected for each:

1. THE BASS STAVE.
(Lines 1, 2, 3, 4, 5.)

Lines G. B. D. F. A.
Spaces A. C. E. G.

2. THE BARITONE STAVE.
(Lines 2, 3, 4, 5, 6.)

Lines B. D. F. A. C.
Spaces C. E. G. B.

3. THE TENOR STAVE.
(Lines 3, 4, 5, 6, 7.)

Lines D. F. A. C. E.
Spaces E. G. B. D.

THE ALTO, COUNTER TENOR (or CONTRALTO) STAVE.
(Lines 4, 5, 6, 7, 8.)

Lines F. A. C. E. G.
Spaces G. B. D. F.

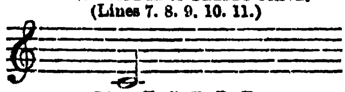
5. The Mezzo-Soprano Stave.
(Lines 5. 6. 7. 8. 9.)

Lines A. C. E. G. B.
Spaces B. D. F. A.

6. The Soprano Stave.
(Lines 6. 7. 8. 9. 10.)

Lines C. E. G. B. D.)
Spaces D. F. A. C.

7. The Fiddle or Treble Stave.
(Lines 7. 8. 9. 10. 11.)



Lines E. G. B. D. F.
Spaces F. A. C. E.

The note shown on each stave is Middle C, *i.e.* the 6th line of the Great Stave. Of these seven staves Nos. 2 and 5 are obsolete, and Nos. 3, 4, and 6 unfortunately are rapidly disappearing. This, in the case of the Tenor and Alto staves, is to be greatly regretted, for music for these voices can readily be written at the proper pitch on their respective staves, whereas with the modern notation, *i.e.* employing the Treble stave for the Tenor and even for Bass songs, the notes, of course, are an octave higher than they are sung. (*See* Score.) When the compass of a piece exceeds that which can be written on the stave, short lines called Leger lines (*q.v.*) are added above or below the stave. With the exception of those above the Treble or below the Bass, these leger lines are simply other lines borrowed from the Great Stave. Hence, the first leger line above the Bass stave C is the same as the first leger line below the treble stave C, and is known as Middle C (*q.v.*) It is unusual to use many leger lines, but when the note or notes are exceptionally high or low, the notes are written respectively an octave lower and the sign 8ve . . . added as an indication that they are to be performed an octave higher than written; or the notes are written an octave higher and 8va bassa . . . added as an indication that they are to be performed an octave lower than written. *See also* Loco.

Stay (*Eng.*) A bar used to strengthen or stiffen a structure. *See also* Strut *and* Tie Rod.

Stayed Link Chain (*Eng.*) A heavy chain in which each link is strengthened by a bar welded to the link, giving the latter the form of the Greek letter θ.

Staying (*Eng., Build., etc.*) Strengthening any object by the addition of stays; boilers, iron roofs, and all large engineering structures supply abundant examples.

Stay Tap (*Eng.*) A long Tap (*q.v.*) used in screwing holes in the shells of boilers for the reception of the ends of stays.

Stay Tubes (*Eng.*) A boiler tube (*see* Boilers) which serves to stiffen the shell of the boiler in addition to its function as a tube.

St. Bees Sandstone (*Geol.*) A local development of the Bunter Series of the Trias or Upper New Red, occurring chiefly in Arran, Ayrshire, Dumfriesshire, Cumberland, and Westmorland. It is well seen at St. Bees, on the Cumberland Coast, near Whitehaven, where, however, only its lowest third remains. The full thickness is to be seen only in Arran and near Ousby in Cumberland, where it amounts to 2000 ft. In the north-west of England it is underlaid by the Bunter Marls, in which the gypsum quarries are worked; and it is overlain there by the Keuper Marls, which are about 900 feet in thickness.

Steady *or* **Back Rest** (*Eng.*) A support used to prevent bending of a long piece of work which is being turned in the lathe.

Steadying Bands (*Cotton Spinning*). Check bands on a mule for keeping the carriage "square" when running out.

Steady Pin (*Eng., etc.*) A dowell (*q.v.*) or projecting pin which prevents the relative motion of two parts of an object.

Steam.—The vapour of water, usually applied to the hot vapour given off at the boiling point (212° F. or higher). True steam is invisible, the white cloud often termed steam being really a collection of fine drops of water formed by condensation. If water be allowed to evaporate into any closed space, the process will go on up to a certain point, beyond which no more vapour will be formed unless the temperature be raised, or the pressure lowered by allowing some of the steam to escape. The steam is then said to be Saturated. Saturated steam can have but one temperature corresponding to any given pressure; but if the steam be removed from contact with the water, its temperature may be raised just as that of any other gas may be; the steam is then said to be Superheated. The relation of the pressure and temperature of saturated steam is thus given by Ewing :—

Temperature (Fahrenheit).	Pressure (lb. per sq. in.).
212°	14·7
230°	20·8
275°	45·5
302°	69·2
347°	129·8
401°	250·3

By plotting a curve with these numbers for abscissæ and ordinates, the pressure of saturated steam for any intermediate temperature can be readily found. The Total Heat of steam is the amount of heat required to raise 1 lb. of water from the freezing point (32° F.) to its boiling point, and then to evaporate it under constant pressure. If t be the temperature of evaporation (or boiling point) then H, the total heat, is given by the equation

$$H = 1091{\cdot}7 + {\cdot}305\,(t - 32°).$$

Saturated steam may be mixed with a certain quantity of water, usually in the form of suspended drops : it is then termed Wet Steam.

Steam Boiler (*Eng.*) *See* Boiler.

Steam Brake (*Eng.*) A form of brake used on locomotives, in which the mechanism for applying the brake block is worked by a cylinder and piston supplied with steam from the boiler.

Steam Chest (*Eng.*) (1) A Valve Box or Chest (*q.v.*) (2) A receptacle on the top of a boiler in which steam can collect, and from which the steam pipe leading to the cylinder runs.

Steam Coal (*Eng.*) Coal suitable for use in boilers. The best form is Anthracite. *See* Coal.

Steam Cock (*Eng.*) In general any tap used for controlling a supply of steam, especially a tap or cock opening into a boiler above the water line. It serves to show, when opened, whether the boiler contains too much water.

Steam Coil (*Build., etc.*) A coil of pipe through which a current of steam flows; used in heating buildings, etc., by steam.

Steam Corner (*Eng.*) The corner of an INDICATOR DIAGRAM (*q.v.*) which shows the end of the process of exhaustion of the steam and the commencement of the admission of fresh steam.

Steam Distillation (*Chem.*) *See* DISTILLATION.

Steam Dome (*Eng.*) A STEAM CHEST (*q.v.*) on top of a boiler.

Steam Economiser (*Eng.*) *See* BOILERS *and* ECONOMISERS.

Steam Engine. The steam engine is a mechanism for obtaining mechanical energy from the heat energy stored up in steam. This heat energy is derived from the combustion of fuel in the boiler fire, and its presence in the steam accounts for the physical change which the water in the boiler has undergone during the process known as evaporation. The steam is produced from water at a pressure considerably above that of the atmosphere, and is delivered to the engine with as little loss of pressure and heat as possible. The higher the pressure of the steam, the greater will be the amount of heat available, in a given weight of steam, for conversion into mechanical energy. Only a fraction of the total heat energy given to the steam in the boiler is converted into mechanical work in the engine. By far the greater portion still remains in the steam after it has passed through the engine. The proportion of heat utilised depends on the thermal efficiency of the engine, amounting from 12 to 15 per cent. in good condensing engines; in the very best engines of large size it may be as high as 20 per cent. The conversion of energy is effected by admitting a quantity of steam into the engine cylinder and allowing it to expand, the expansion causing the piston to be pushed forward. The displacement, or stroke, of the piston is limited to a fixed length by the crank; and at the end of the stroke the space occupied by the steam will be from twice to four times the original volume, or even more. During expansion both the pressure and temperature of the steam are lowered, and the heat energy is reduced by an amount equivalent to the work done by the steam in pushing the piston and the mechanism attached to it through the distance represented by the stroke. This process is repeated at each successive stroke of the engine, so that the supply of steam passing through the engine approximates to a steady

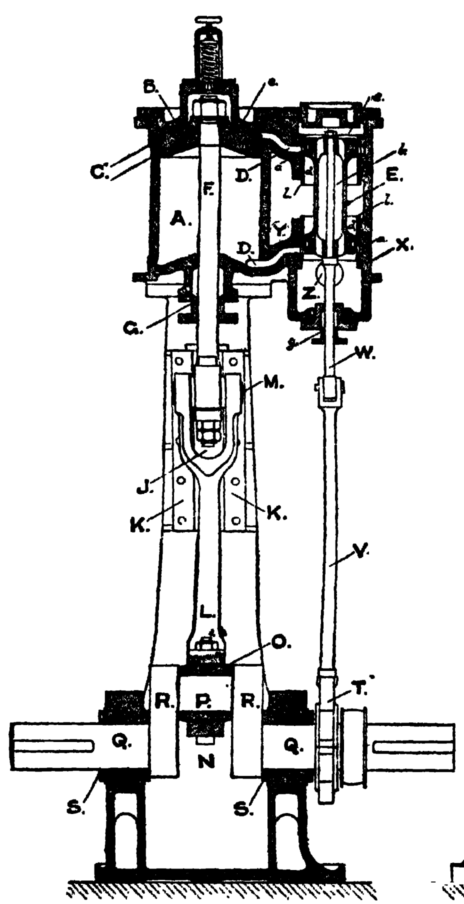


FIG. 1. VERTICAL SIMPLE ENGINE. FRONT SECTIONAL ELEVATION.

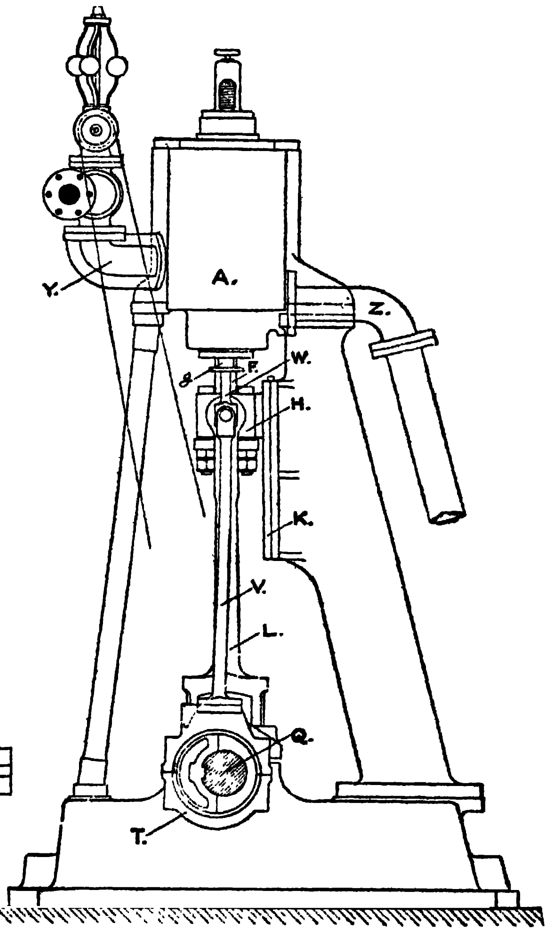

FIG. 2. VERTICAL SIMPLE ENGINE. SIDE ELEVATION.

flow. The engine consists of a hollow **CYLINDER A** (*see* figs. 1 and 2), closed at both ends; inside it is the **PISTON B**, a sliding partition which fits the bore of the cylinder sufficiently closely to prevent the steam leaking past it, but having sufficient freedom to allow it to move from end to end of the cylinder with as little friction as possible. This is effected by the **PISTON RINGS C**, which are made slightly larger in diameter than the cylinder bore, but have a sufficient portion of their circumference cut away to allow of their being sprung into the cylinder. Passages, or **PORTS, DD**, are provided at the ends of the cylinder, by which the steam can enter or leave. These ports are opened and closed by the **SLIDE VALVE E**, the movement of which is actuated by the piston in the manner described below. The **PISTON ROD F**, which is rigidly attached to the piston, is of circular section, and has its centre line concentric with the piston and cylinder. It passes out through one end of the cylinder, and is somewhat longer than the latter, so that a portion of its length is always outside the cylinder. By this means the connection is made between the piston and the external moving parts of the engine. The hole in the cylinder end, through which the rod projects, is made steam-tight by the **GLAND G**, which fits round the rod closely, at the same time producing as little friction as possible. The external end of the rod is rigidly attached to the **CROSSHEAD H**, a block sliding on the **FACING J**, to which it is held by **GUIDES K K**, the arrangement serving to keep the axis of the piston and piston rod in line with that of the cylinder. If the engine is intended to produce rotary motion, the crosshead has a **CONNECTING ROD L** attached to it by means of the **CROSSHEAD PIN M**. This pin passes through the end of the connecting rod and the centre of the crosshead, forming a joint, so that the rod is free to follow the movements of the **CRANK N**, to which the other end of it is attached. A bearing O is provided at the crank end of the connecting rod, in which the **CRANK PIN P** rotates as the **CRANK SHAFT Q** revolves. The crank pin, **CRANK CHEEKS RR**, and shaft all form one rigid piece, which is carried in the **CRANK SHAFT BEARINGS SS**, placed as near to the crank as possible. On the shaft, close to one of the bearings, is fixed the **ECCENTRIC T**, which actuates the **SLIDE VALVE E** by means of the **ECCENTRIC ROD V** and **VALVE ROD W**. The valve rod passes through a **GLAND** *g* into the **VALVE CHEST X**, and is rigidly attached to the valve. The latter (shown in the form known as the **PISTON SLIDE VALVE**) fits the **LINERS** *l l* much in the same way as the piston fits the cylinder. It, however, fits only along the two end portions of its surface, the intermediate portion being recessed to a smaller diameter, in order that the annular space thus formed may serve as a passage for steam in certain positions of the valve. Y is the **STEAM INLET PIPE**, and from it, when the valve is in the right position, steam can enter the top portion of the cylinder *o* by means of the annular space *d*, which is formed between the liner *l* and the middle portion of the valve body, thence through the hole *a* in the liner and along the port D. The admission of steam into the bottom portion of the cylinder, on the upstroke, is similar. Z is the **EXHAUST PIPE**, by which the steam on leaving the cylinder passes away to the condenser or escapes into the atmosphere. From the upper port D, its passage is by means of the hole *a* to the top part of the valve chest *c*, thence through the hollow portion of the valve body *b*, into the lower part of the chest and out at Z. From the bottom port the steam passes through the hole in the liner direct into the lower part of the valve chest and out at Z. The action of the engine is as follows: When the piston is at the top of its stroke, the position of the valve is such that **ADMISSION** of steam takes place from the body of the valve chest to the space *o*, and the pressure of the steam tends to force the piston downwards. If the engine shown in figs. 1 and 2 were at a standstill, with the piston at the top of its stroke, no movement would take place, as the crank is on the **DEAD CENTRE** (*q.v.*) The engine must be assumed to be already in motion. During the downward movement of the piston, steam continues to flow into the top of the cylinder till a certain fraction of the stroke is reached, when the valve closes the hole *a*, and the supply of steam is **CUT OFF**. The imprisoned volume of steam then begins to expand, pushing the piston farther downwards, though with continually diminishing pressure, till its stroke is nearly completed, when the valve opens the top port D to the exhaust. Just before the piston comes to the end of its stroke, the lower port D is opened to steam by the valve, and the same process is repeated in the bottom portion of the cylinder during the upstroke. While the greater portion of the upstroke is taking place the top port remains open, and the steam continues to **EXHAUST** until the piston is near the top of its stroke, when the valve closes the port again. The imprisoned steam is then compressed during the remainder of the stroke, its pressure at the same time continually rising. This **COMPRESSION** produces a cushioning effect, which assists the reversal of the motion of the piston, and also tends to improve the thermal efficiency of the engine by reducing clearance losses and initial condensation. As the piston gets to the top of its stroke the valve again opens and admits steam above it, and the whole process of admission, cut off, exhaust, and compression is repeated.

There are many different types of engines, the particular design depending generally on the class of work for which the engine is intended; but distinct types are often employed for the same kind of work. For the purpose of dealing with the chief points of difference the following several classifications are employed:

I. Condensing and Non-Condensing.
II. Simple, Compound, and Multiple Expansion.
III. High Speed and Slow Speed.
IV. Vertical, Horizontal, Beam, Rotary, etc.
V. Marine, Locomotive, Electric Generating, Pumping, Mill Driving, Winding, etc.

I. *Condensing and Non-Condensing Engines.*—A **CONDENSING ENGINE** is one in which the steam, on leaving the cylinder, exhausts into a condenser, where the pressure is maintained as much below that of the atmosphere as possible. By this means the back pressure, *i.e.* the retarding pressure on the other side of the piston, is reduced, and it is possible to have a higher degree of expansion in the cylinder, and so to convert a larger fraction of the heat energy contained in the steam into mechanical work, than is the case with the **NON-CONDENSING ENGINE**. The latter simply exhausts its steam into the atmosphere, and can, therefore, only have the expansion carried to a pressure slightly above that of the atmosphere.

II. *Simple Engines, Compound and Multiple Expansion Engines.*—In the engine shown in figs. 1 and 2, and described above, the whole expansion of the steam takes place in one cylinder. The amount of expansion or "number of expansions" is the

ratio of the volume occupied by the steam at the beginning of the exhaust, to that occupied at the moment of cut off; and it would at first sight appear that this is only limited by the relative amounts of the pressure of the steam supplied to the engine, and the pressure of the atmosphere or condenser into which it exhausts, and that the best results would be obtained when the ratio of expansion was as near to this limit as possible. It is found, however, that beyond a certain point the gain by increased expansion is more than counterbalanced by other losses, both mechanical and thermodynamic, which are introduced, and also by the increased size and cost of the engine. By allowing the steam, after exhausting from one cylinder, to expand further in a second cylinder, both pistons being connected to the same shaft, the ratio of expansion giving the best economy is considerably increased, and with it the thermal efficiency of the engine. An engine with two cylinders arranged in this way is called a COMPOUND ENGINE (*see* figs. 5, 7, etc.), while an engine in which the expansion is completed in one cylinder is called a SIMPLE ENGINE (*see* figs. 3, 4, 10, etc.) The expansion may be still further increased with advantage in large condensing engines by employing three cylinders, in each of which successive

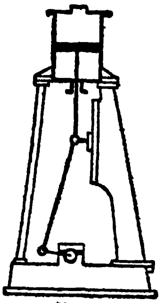

FIG. 3.
VERTICAL ENGINE.

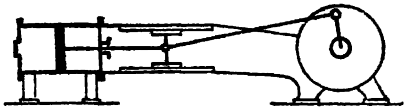

FIG. 4—HORIZONTAL ENGINE.

stages of the expansion take place. An engine of this sort is known as a TRIPLE EXPANSION ENGINE (*see* fig. 6). QUADRUPLE EXPANSION

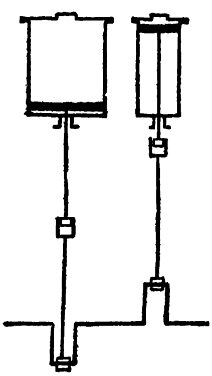

FIG. 5.
COMPOUND ENGINE

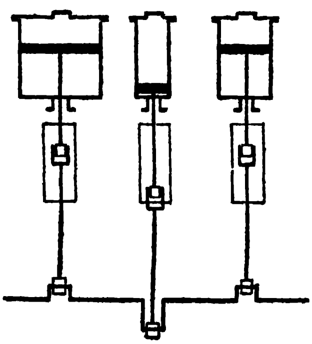

FIG. 6.
TRIPLE EXPANSION ENGINE.

ENGINES, in which there are four cylinders, each forming a separate stage of the expansion, are also built, chiefly for the largest class of marine work.

III. *High and Slow Speed Engines.*—This classification is a rather indefinite one; the size of an engine must be taken into consideration as well as the actual speed in determining which of these classes it belongs to. Up to 70 or 80 double strokes per minute would be considered a slow speed in a small engine, while in one of very large size it would be considered high. The engines of torpedo-boat destroyers, and some of the smaller engines for driving electric generators, run at as many as 400 to 600 revolutions per minute, and are considered very high speed. Large pumping engines only make from 20 to 40 double strokes per minute, and are probably the slowest type of engine built.

IV. *Vertical, Horizontal, Beam, Rotary, and Other Engines.*—Engines are classed as VERTICAL or HORIZONTAL according as the axes of their cylinders are vertical or horizontal (*see* figs. 3 and 4). Some

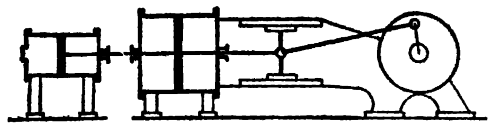

FIG. 7.—TANDEM ENGINE.

engines have one cylinder vertical and the other horizontal, as shown in fig. 9. BEAM ENGINES may

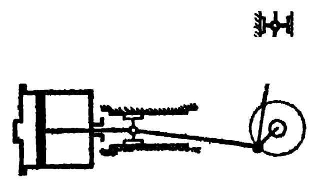

FIG. 8.
COMBINED VERTICAL AND HORIZONTAL ENGINE.

have either vertical or horizontal cylinders. The pistons and driven mechanism are connected to the

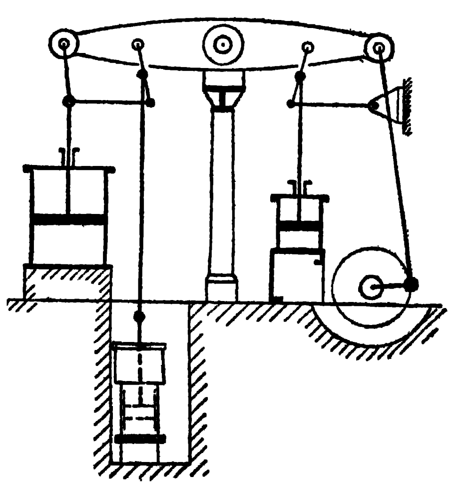

FIG. 9.
COMPOUND BEAM ENGINE WITH AIR PUMP.

ends of a large beam, supported by a shaft passing through its midpoint. When the engine is a vertical one the beam is straight, as shown in fig. 9; and when horizontal the beam is made in the form of a bell crank, as shown in fig. 10. The straight

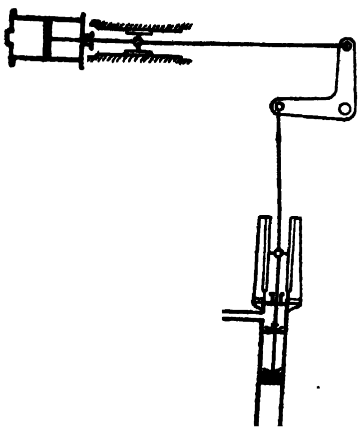

FIG. 10.—PUMPING ENGINE WITH QUADRANT BEAM.

beam is the more usual type, but both are now nearly obsolete. The BROTHERHOOD ENGINE consists of three cylinders placed with their axes at 120° to one another, as shown in fig. 11, all three connecting rods being coupled to a common crank pin. The pistons are single acting, *i.e.* the steam is admitted to one side only, and the body of each piston is lengthened out, so that no crosshead or piston rod is required. The cylinders of both horizontal and vertical engines are often placed one behind the other with their axes in line, so that a common piston rod serves for both. An arrangement of this sort is known as a TANDEM ENGINE (*see* fig. 7), as distinguished from the SIDE-BY-SIDE type, shown in fig. 5. A ROTARY ENGINE is one in which the motion of the piston is rotary, instead of taking place in a straight line; but the term is sometimes applied also to all engines producing rotary motion. There are a good many types of this class, but they are not used to any great extent for practical purposes. The general principle of the rotary engine is shown in fig. 12. A modification of this class is the SPHERICAL ENGINE.

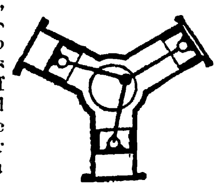

FIG 11.
BROTHERHOOD ENGINE.

V. *Marine, Locomotive, Electric Generating, Pumping, Mill Driving, Winding, and Other Engines.* — In many cases distinct types of engines have been developed to perform particular duties or to work in special positions. MARINE ENGINES are probably the most numerous class, and are built in sizes far exceeding those of any other type. They are condensing engines, and are either compound, triple, or quadruple expansion. For driving screw vessels the vertical type is used, with the cylinders above the shaft. For small paddle steamers the cylinders are usually below the shaft, and, as the height of the latter above the bottom of the boat is limited, the cylinders are fixed on trunnions, which allow them to oscillate and follow the movement of the crank, thereby dispensing with crossheads and connecting rods. In large paddle boats the cylinders are fixed at an angle to the horizontal, crossheads and connecting rods being used. This is known as the DIAGONAL type. LOCOMOTIVE ENGINES are, from the nature of their work, always horizontal and non-condensing. They consist of two or more cylinders, the cranks being placed at right angles for two cylinders in order that the engine may be able to start in any position of the cranks. A considerable number of locomotives are built with compound engines. ENGINES FOR DRIVING ELECTRIC GENERATORS are of many different types. In large sizes they are compound or triple expansion, and, where possible, are condensing engines. Both horizontal and vertical engines are used, but the latter type is becoming the more common of the two. Its advantage lies in the saving of floor space, owing to the smaller area occupied and the fact that, on account of the higher speed at which it can be run, the engine shaft can be coupled direct to that of the generator, instead of requiring a rope or belt drive, as is the case with horizontal engines. PUMPING ENGINES of recent design are arranged to drive direct, *i.e.* the piston rod of the engine is in line with and rigidly attached to that of the pump (*see* Fig. 13). Very often a flywheel is attached, by means of a connecting rod or rods, to a crosshead fixed at some convenient point on the piston rod. Both vertical and horizontal engines are employed for pumping. In the older types, beam engines, with either straight or quadrant beams, were used. For MILL DRIVING, compound or triple expansion engines are employed, and are almost always condensing. The horizontal type is most largely used for this class of work, although vertical engines and, in a good many instances, beam engines, are also employed. WINDING ENGINES are used for lifting coal or other minerals to the surface, and are always horizontal. In a few recent instances they are arranged to work condensing, but the usual type is non-condensing. Tandem compound engines are sometimes employed for the heaviest class of winding. Except in very old engines, all sizes are built with two cylinders or sets of cylinders arranged one on each side of the winding drum, the cranks being fixed at right angles.—W. B. S.

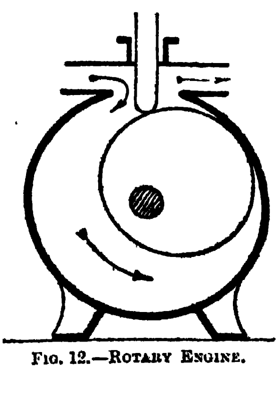

FIG. 12.—ROTARY ENGINE.

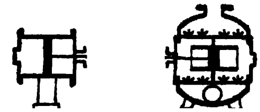

FIG. 13.—PUMPING ENGINE.

Steam Engine Indicator (*Eng.*) *See* INDICATOR DIAGRAMS.

Steam Gauge (*Eng.*) An instrument for measuring the pressure of steam. In the most usual form steam is admitted into a tube of elliptical section, closed at one end and bent into a circle; this tube tends to straighten out under the action of the pressure inside, and a certain amount of movement of the end of the tube is produced. This movement is transmitted to an indicating lever or arm, by

which it is magnified; the free end of the arm moves over a dial whose divisions show the actual pressure of the steam inside the bent tube.

Steam Hammer (*Eng.*) This consists essentially of a heavy mass of iron or steel, moving in vertical guides and raised by means of a rod and piston working in a steam cylinder placed vertically above the guides. The hammer is raised by means of steam admitted to the cylinder, and either falls by its own weight, or else the force of the blow is modified by admitting steam above or below the piston. So perfect is the control which a skilled man can exert over a steam hammer that a nut can be cracked on the anvil without injury to the kernel. Steam hammers are used in all heavy forging operations.

Steam Hammer Type (*Eng.*) An engine of the marine type, in which the framework resembles the form of a steam hammer. *See* STEAM ENGINES.

Steaming (*Eng.*) (1) Getting up steam in a boiler. (2) As applied to a steamship, propelled by its own engines. (3) In general language, giving off steam or vapour.

—— (*Textile Manufac.*) Process of blowing the cloth with steam after pressing, to take off the excessive gloss or glaze.

Steam Jacket (*Eng.*) A hollow casing round the cylinder of an engine. The space between the cylinder and the jacket is kept supplied with hot steam from the boiler, in order to maintain the temperature of the cylinder, and thus prevent condensation of the steam inside the latter.

Steam Jet (*Eng.*) A current of steam issuing from an opening or nozzle. It is used for various purposes: to supply water vapour in the production of various kinds of producer gas, to aid the production of draught through the furnace in locomotives, to clear noxious gases out of a well or shaft, etc.

Steam Joints (*Eng.*) Joints in engines, steam pipes, etc., which are rendered steam-tight by the use of suitable packing materials. The material used must be one which can be forced by pressure into the interstices of the joint, and which will not afterwards crack, shrink, nor decompose rapidly. Rubber, various fabrics, and soft metals, such as lead or copper wire, are used.

Steam Lap (*Eng.*) *See* SLIDE VALVE.

Steam Line (*Eng.*) The upper horizontal part of an INDICATOR DIAGRAM (*q.v.*), which shows the entrance of steam at uniform pressure.

Steam Nozzle (*Eng.*) The jet by which steam is discharged into the chimney of a locomotive, in order to increase the draught through the furnace.

Steam Passages (*Eng.*) The PORTS of a steam cylinder. *See* STEAM ENGINE *and* SLIDE VALVE.

Steam Pipes (*Eng.*) The pipes, of iron or copper, which lead steam from the boiler to the cylinder of an engine.

Steam Ports (*Eng.*) *See* STEAM ENGINE *and* SLIDE VALVE.

Steam Pressure. *See* STEAM.

Steam Reversing Gear (*Eng.*) A small subsidiary cylinder for actuating the gear which moves the slotted link in the valve gear of large engines that have to be reversed; it is chiefly employed in large marine engines.

Steam Space, Steam Room (*Eng.*) The space in a boiler which is not occupied by water. Its volume varies with the conditions under which steam has to be supplied.

Steam Tight (*Eng.*) A joint through which steam cannot leak when the material of the pipe, etc., is hot, is said to be steam-tight.

Steam Trap (*Eng.*) An arrangement for intercepting water which is carried over from the boiler by steam, or which is condensed in the pipes. In many forms of trap there is an automatic valve to allow the water to escape after a certain quantity has accumulated.

Steam Turbine (*Eng.*) *See* TURBINE, STEAM.

Steam Valve (*Eng.*) Any valve for controlling the flow of steam, *e.g.* a SLIDE VALVE (*q.v.*)

Steam Whistle. A whistle in which sonorous vibrations are set up by a sharp-edged sheet or tube of metal, on which a jet of live steam impinges.

Stearic Acid (*Chem.*) $CH_3.(CH_2)_{16}.COOH$. White shining plates or needles; melts at 69·2°; boils at 291° under 100 mm. pressure; insoluble in water; sparingly soluble in cold alcohol; much more soluble in hot alcohol; soluble in ether and benzene. Heated with phosphorus pentoxide it gives stearone $(C_{17}H_{35})_2CO$. Occurs as glyceryl ester, tristearin, in many animal and vegetable fats and oils. Its sodium salt is the chief constituent of good soap. It is made by melting and filtering beef or mutton suet, saponifying the suet by boiling with caustic soda solution; decomposing the soap with hydrochloric acid; crystallising from hot alcohol; the pressed crude acid is boiled with an alcohol solution of magnesium acetate, when a precipitate of magnesium stearate forms, which is decomposed by boiling with hydrochloric acid, and the stearic acid so obtained is crystallised from alcohol. *See* SOAP.

Stearin (*also called* TRISTEARIN) (*Chem.*) One of the chief constituents of all solid vegetable and animal fats. *See* FATS. It crystallises from ether in shining leaves. When heated it melts first at 55°, and undergoes contraction, and on further heating it solidifies, and melts again at 72°. Slightly soluble in cold alcohol; more soluble in hot alcohol; soluble in ether. Distils unchanged under reduced pressure. Ordinary stearin always contains tripalmitin. Pure stearin is made from monostearin,

$$C_3H_5 \begin{array}{l} O_2C_{18}H_{35} \\ OH \\ OH \end{array}$$

(from glycerine and stearic acid) by heating it with stearic acid in excess at 270°. Stearin is largely used for making fatty acids in candle making.

Steatite *or* **Soapstone** (*Geol.*) A hydrous magnesian silicate usually occurring in connection with beds of serpentine which have undergone dynamic metamorphism. Chromite, and also Magnetite, are not uncommonly associated with it. It may be regarded as a massive form of Talc.

Steel. The chemistry and metallurgy of steel are described under IRON; definitions are also given under this head of the chief varieties of steel, and of the various processes by which they are produced (*e.g.* OPEN HEARTH, SIEMENS-MARTIN, *and* BESSEMER PROCESS). The effect of the addition of various elements—*e.g.* manganese, chromium, and nickel—is also dealt with.

The employment of steel has increased very greatly in recent years. Originally its chief use was for cutting tools, weapons, springs, etc., where its properties of hardening and tempering were essential, and in all these respects steel still holds its position. It is in the use of CAST STEEL and MILD STEEL that the greatest progress has been made. Castings are largely made from steel produced by the Open Hearth Process (*see* IRON), the process differing but little from the ordinary method of making iron castings. Good steel castings are somewhat more difficult to produce than those of iron, and require annealing after withdrawal from the mould; they however, possess greater strength. MILD STEEL closely approaches wrought iron in composition and properties; like wrought iron, it can be welded, and cannot be hardened nor tempered. It can be used for practically all the purposes for which wrought iron is usually employed, *e.g.* plates for boilers, ships, girders, the production of thin sheets, drums, pipes, wire, rivets, and for a variety of electrical work.

Steel Castings (*Met., etc.*) *See* STEEL.

Steel Facing (*Eng.*) A layer or plate of steel welded on to the iron body of an anvil, hammer, etc., to produce a hard external surface.

Steel, Harveyised. *See* IRON (*Chem.*)

Steeling (*Eng.*) The operation of facing with steel. *See* STEEL FACING.

Steel, Mild. *See* IRON (*Chem.*)

Steel Ropes (*Eng.*) Ropes made of thin twisted steel wire. *See also* WIRE ROPES.

Steelyard. A device for weighing, consisting of a lever of the first kind: the object to be weighed is suspended from the short arm and a small movable weight is moved along the other arm (which is graduated) till the lever is in equilibrium. The weight is then read off on the graduated scale.

——, **Danish.** A modified form of steelyard in which a constant weight is fixed at one end, and the fulcrum is movable.

Steening, Steining, *or* **Steaning** (*Mining, etc.*) Lining the walls of a shaft or well with brickwork or masonry, in order to prevent irruption of the surrounding soil.

Steeple (*Architect.*) The tower of a church, together with its spire or lantern.

Steering. (1) Directing or guiding the motion of a vessel or vehicle. (2) Turning a crane, etc., about its vertical pivot; more often termed SLEWING (*q.v.*)

Steering Gear. (1) Mechanism for moving the rudder of a ship, the axle or steering wheels of a vehicle, etc. (2) The toothed wheels employed in slewing a crane.

Stele, Stela (*Architect. and Archæol.*) (1) An upright stone; the term generally denotes the Greek tombstone, which was usually a vertical slab tapering upwards and crowned with an ornament similar to an antefixa, and known as the stele crest, above a simple cornice. Stelæ were also used for public purposes, *e.g.* for displaying laws and decrees, or as boundary marks. They constitute interesting relics of Greek and Roman art, being often elaborately sculptured. *Cf.* CIPPUS. (2) The shaft or wooden part of an arrow, *i.e.* without feathers or head, was termed the stele.

Stencil *or* **Stencil Plate.** (1) A thin plate (usually of metal) having letters or other designs cut through it; by rubbing a brush charged with some kind of thick ink or paint over the plate the design can be reproduced on a surface against which the plate is held. (2) The letters or designs so produced.

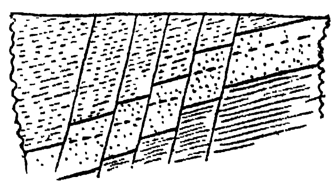
Stencilling (*Dec.*) The art of ornamenting by means of stencil patterns. Stencilling is usually done in distemper, but sometimes in oil colour, by means of a stiff brush, the stencil pattern being held in position by needle points. Frequently two or more colours are used in a stencil ornament, a different stencil being used for each colour. During the last few years stencilled friezes on paper and various textiles have come largely into use. These are prepared by some of the wallpaper manfacturers, and are usually executed in blended colours. The stencil plates being made of heavy copper, their weight is sufficient to hold the paper or texile in its place while stencilling is executed. A large brush filled with colour is employed, and, being pressed heavily upon the pattern, the colour is left very strong. When the brush is raised the colour becomes less well defined. Portable stencil decorations will doubtless remain popular for some considerable time.

Stenter (*Lace Manufac.*) An ingenious improvement in the principle of machinery for dressing lace curtains whereby it becomes a continuous process. The breadth of lace curtain having undergone the preliminary processes of colouring and starching, is fed into the stenter at one end in its wet state, and comes out at the other end thoroughly dried, stiffened, and calendered.

Stenter Feeder. One of the operatives who manipulates the clips that grasp the selvages of the lace curtain as it enters the stenter (*q.v.*)

Step (*Eng.*) (1) A FOOTSTEP BEARING (*q.v.*) (2) The difference between the radii of consecutive pulleys forming a stepped or coned pulley.

Step Faults (*Geol.*) The dislocation accompanying a fault is rarely quite simple in character. More often the disruption is the cumulative effect of a number of small faults running parallel to each other, and having a common direction of downthrow; so that their traces, when seen in elevation, appear like steps.

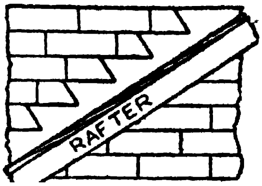


STEP FAULT.

Stephanite (*Min.*) A silver sulph-antimonide, $5Ag_2S.Sb_2S_3$; silver=68·5, antimony=15·3, sulphur =16·2 per cent. Orthorhombic, often massive in indefinite masses scattered through the matrix; colour iron black, with metallic lustre. From many silver mines of Central Europe in small quantity; from Mexico, Peru, etc.

Steppe Conditions (*Geol.*) Desert conditions (*q.v.*) such as those which occur in the elevated tracts of Central Asia.

Stepped Flashing (*Plumb.*) Lead or zinc cut in the form of steps and pinned into the joints at the angle where a roof meets a wall.



STEPPED FLASHING.

Stepped Gearing (*Eng.*) Toothed wheels in which there are two or more parallel rows of teeth, the teeth in the second row being slightly in front of those in the first, and so on. A tooth in any one row comes into action before the corresponding one in the previous row is completely disengaged, and thereby the relative motion of the two wheels is made more steady and the stresses less violent than in ordinary gearing.

Stepped Resistance (*Elect.*) An electrical resisttance which can be increased or diminished by definite amounts at a time; usually composed of a number of coils in series, so connected that one, two, three, etc., may be included in the circuit at will.

Stepping Round (*Eng., etc.*) Dividing the circumference of a circle into a number of equal parts, by means of dividers or compasses.

Steps, Balanced (*Carp. and Join.*) *See* BALANCED STEPS.

Step Up Transformer (*Elect. Eng.*) A transformer in which the induced or secondary E.M.F. is greater than the primary E.M.F. *See* TRANSFORMERS.

Stère. *See* WEIGHTS AND MEASURES.

Stereo (*Print.*) An abbreviation of the word STEREOTYPE (*q.v.*)

Stereochemistry. As chemical formulæ are ordinarily written, it would appear as if all the atoms which go to form the molecule of a compound are in one plane. This is probably never the case. Consider the compound methylene chloride (CH_2Cl_2): if all the atoms lie in one plane, we should have two compounds of this formula,

$$\begin{array}{c} H \\ | \\ H-C-Cl \\ | \\ Cl \end{array} \text{ and } \begin{array}{c} Cl \\ | \\ H-C-H, \\ | \\ Cl \end{array}$$

whereas only one compound is known. That only one compound of the formula CH_2Cl_2 exists is accounted for by assuming that the carbon atom occupies the centre of a regular tetrahedron, while the four atoms in union with it are attached at the angular points. The same assumption is made to explain the optical behaviour of compounds which contain an asymmetric carbon atom (*see* ASYMMETRIC CARBON ATOM); and a similar assumption is made to explain the optical behaviour of certain selenium, sulphur, and tin compounds. *See* the respective elements. The determination of the arrangement of the atoms of a molecule in space and the solution of certain problems arising out of this is called Stereochemistry. One important problem of Stereochemistry is that of Stereoisomerism (*q.v.*) The other problems relate to the influence which the space-arrangement of the various atoms or groups in a molecule exercises on the course of reactions. A few examples are added. Let a series of tetrahedra be joined together in such a way that the centres of the first and second are in a straight line, the centres of the second and third in a straight line, and so on; then it will be found that of all the tetrahedra up to five the angular points of the first and fifth are nearest together, and if a sixth tetrahedron is added, its free angular points will be nearer to those of the first one than any of the others, except the fifth. Corresponding to this is the ease of formation and stability of five and six carbon atom ring compounds. Thus, on distilling the sodium salts of the homologues of the oxalic acid series, the first member to give a ring compound, molecule for molecule is adipic acid.

$$CH_2\begin{array}{l} \diagup CH_2.COONa \\ \diagdown CH_2.CH_2.COONa \end{array} = CH_2\begin{array}{l} \diagup CH_2.CO \\ \diagdown CH_2.CH_2 \end{array}\Big| + CO(ONa)_2.$$

Ketopentamethylene.

Pimelic acid gives ketohexamethylene.

$$CH_2\begin{array}{l} \diagup CH_2-CH_2.COONa \\ \diagdown CH_2-CH_2.COONa \end{array} = CH_2\begin{array}{l} \diagup CH_2-CH_2 \\ \diagdown CH_2-CH_2 \end{array}\!\!>CO + CO(ONa)_2.$$

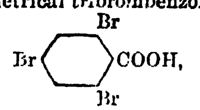
In the same way the easy formation of γ- and δ-lactones may be explained.

In the conversion of the following acids

$$\begin{array}{c} H \\ | \\ H-C-H \\ | \\ COOH \end{array} \quad \begin{array}{c} H \\ | \\ H-C-CH_3 \\ | \\ COOH \end{array} \quad \begin{array}{c} CH_3 \\ | \\ H-C-CH_3 \\ | \\ COOH \end{array} \quad \begin{array}{c} CH_3 \\ | \\ H_3C-C-CH_3 \\ | \\ COOH \end{array}$$

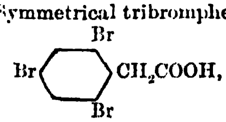
into esters there is a diminution in the speed of the reaction from left to right, acetic acid forming an ester at a higher rate than propionic, etc. This is to be attributed to the fact that the space round the carboxyl group is less filled in the case of acetic acid than in that of propionic acid, and so on; and therefore the entrance of the alkyl group is more and more difficult as we proceed from acetic to trimethylacetic acid. Again, triphenylacetic acid esterifies much more slowly than diphenylacetic acid. In the benzene series the ortho-positions play the same part as the α-position in the above series of acids, as is shown by the following example:—

Symmetrical tribrombenzoic acid,



gives no ester.

Symmetrical tribromphenylacetic acid,



gives 99 per cent. ester.

Just as ester formation is retarded, so also is the process of hydrolysis. An example of this kind is given under NITRILES (*q.v.*) Nitrogen compounds furnish good examples of this steric hindrance to reaction: aniline is a weak base, but forms many salts; diphenylamine forms very few salts; triphenylamine forms no salts; tetraphenylammonium compounds do not exist. The following example clearly shows that the addition of alkyl iodide cannot take place for want of space in benzyldiphenylamine:—

$$\begin{array}{l} C_6H_5 \\ | \\ N-CH_2C_6H_5 \\ | \\ C_6H_5 \end{array} \text{ will not combine with methyl iodide.}$$

Benzyldiphenylamine.

$CH_2C_6H_5$
|
$N-CH_2C_6H_5$ combines with difficulty with methyl iodide.
|
C_6H_5
Dibenzylaniline.

$CH_2C_6H_5$
|
$N-CH_2C_6H_5$ combines readily with methyl iodide.
|
$CH_2C_6H_5$
Tribenzylamine.

See also under SEMIDINE TRANSFORMATION.

Stereography (*Art*). The art of drawing solid bodies on a plane surface: perspective.

Stereoisomerism (*Chem.*) Isomerism caused by a difference in the arrangement in space only, of the same atoms or groups of atoms in a molecule, their mode of union remaining the same. The compounds

$$\begin{array}{ccc} CH_2Cl & & CH_3 \\ | & \text{and} & | \\ CH_2Cl & & CHCl_2 \\ \text{Ethylene chloride.} & & \text{Ethylidene chloride.} \end{array}$$

are isomeric, but not stereoisomeric, because the mode of union of the chlorine atoms is not the same, there being one united to each carbon atom in ethylene chloride and two united to the same carbon atom in ethylidene chloride. The two forms of

$$\begin{array}{c} CH_2COOH \\ | \\ H-C^*-COOH \\ | \\ OH \end{array}$$

malic acid, namely, dextrorotatory and lævorotatory, are stereoisomers, because in both we have the same atoms and groups of atoms similarly combined, but there is a difference in the space arrangement of the four groups attached to the carbon atom marked *. The elements which form stereoisomeric compounds are carbon, sulphur, selenium, tin, nitrogen; the explanation of this property in the case of carbon is given by the theory of the asymmetric carbon atom. *See* ASYMMETRIC CARBON ATOM. A similar explanation is given for sulphur, selenium and tin, but no generally accepted explanation for nitrogen has been offered yet. Examples of compounds containing one asymmetric carbon atom are: lactic acid, mandelic acid, amyl alcohol, malic acid, pinene, leucine. *See all these.* For sulphur, selenium, tin, *see under* the respective elements. When there is only one asymmetric atom in a compound, the latter is known in three forms, namely, the dextrorotatory form, the lævorotatory form, and an optically inactive form obtained by mixing equal quantities of the dextro- and lævo-forms. When there are two asymmetric carbon atoms in a compound, more than three forms can exist; denoting the two carbon atoms by A and B and the dextro arrangement of A by $+A$, the lævo arrangement by $-A$, and similarly for B we have the following forms:

$$\begin{array}{cccc} +A & +A & -A & -A \\ +B & -B & +B & -B \end{array}$$

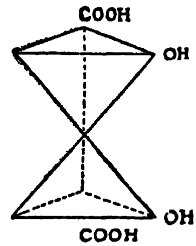
without counting racemic forms, of which there will be two. Suppose the same groups are attached to each carbon atom, then we have:

$$\begin{array}{cccc} +A & +A & -A & -A \\ +A & -A & +A & -B \end{array}$$

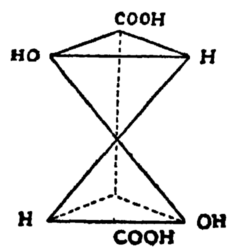
In this case there are three forms only, not counting the single racemic form, because the two middle arrangements are identical. The $\begin{smallmatrix} +A \\ -A \end{smallmatrix}$ arrangement is optically inactive because the dextrorotatory power of the one half of the molecule is compensated by the lævorotatory power of the other half of the molecule. This kind of compound is said to be inactive by internal compensation; it is also called a meso-compound. An example of each of these two classes of two asymmetric carbon atom compounds is given:

$$\begin{array}{ccc} CH_2OH & & COOH \\ | & & | \\ H-C-OH & & H-C-OH \\ | & & | \\ H-C-OH & & H-C-OH \\ | & & | \\ CHO & & COOH \\ \text{A four carbon-atom sugar.} & & \text{Tartaric acid.} \end{array}$$

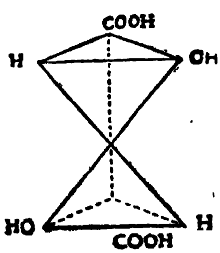
The tetrahedral formula for tartaric acid may be written



To decide which form of tartaric acid is represented by the diagram, let a plane be drawn through the common angular point and parallel to the opposite faces of the tetrahedra; then if the plane divide the figure symmetrically the compound is inactive; thus the above figure represents mesotartaric acid. By interchanging any two groups in the upper tetrahedron we get



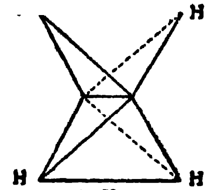
which is lævotartaric acid if the upper tetrahedron in the first formula was dextrorotatory; similarly, if any two groups in the lower tetrahedron in the first formula (assuming the upper one to be dextrorotatory) were interchanged, we should have



which would be dextrotartaric acid. Instead of drawing tetrahedra we may represent the formulæ of these compounds by supposing the groups to be projected on to the plane of the paper, and this is commonly done to save space. Thus we may represent the tartaric acids as follows:

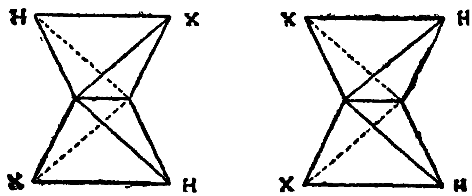
Dextrotartaric acid.	Lævotartaric acid.	Mesotartaric acid.
COOH	COOH	COOH
|	|	|
H—C—OH	HO—C—H	H—C—OH
|	|	|
HO—C—H	H—C—OH	H—C—OH
|	|	|
COOH	COOH	COOH

Racemic tartaric acid, commonly called racemic acid, is formed from equal quantities of the dextro- and lævo-acids. The five and six carbon atom sugars furnish examples of carbon compounds which contain more than two asymmetric carbon atoms. When equal quantities of dextro- and lævo-modifications of the same substance are mixed, the resulting inactive product may, in the case of solids, be a mere mixture of the two substances, or mixed crystals may be obtained, or chemical union may occur, and a true racemic compound be formed. Chemical reaction will not distinguish between the three cases; they are distinguished by their behaviour on melting and solution. The inactive mixture will melt below either of its components or any other mixture of them, and addition of either component to it will raise its melting point; the racemic compound will have a melting point either above or below that of its components, but addition of either component will lower it till a certain excess is added, when it will raise the melting point. In the case of the inactive mixed crystal this may melt at the same temperature as its components, or behave as the inactive mixture, or have a melting point above that of its components, in which last case addition of either component will lower it constantly to the melting point of its components. As a racemic compound may only be stable through a limited range of temperature, the melting point determination only gives information as to the state of the substances about the melting point. Hence solubility determinations are important. To distinguish between an inactive mixture and a racemic compound a saturated solution is made at a given temperature with the inactive compound, and another saturated solution at the same temperature is made with the inactive substance plus one component. In the case of the mixture both solutions will be identical and inactive; in the case of the racemic compound one will be inactive and the other active. As an example may be given sodium ammonium tartrate, which will be found to form an inactive mixture if crystallised below 28°, but a racemic compound if crystallised above 28°. When compounds containing asymmetric atoms of any kind are synthesised, the inactive form is always obtained. These inactive forms can be resolved into their components: (1) by the use of ferments of various kinds, (2) by the use of other optically active substances, (3) by taking advantage of a difference in the speed of esterification. For examples, see under the individual substances mentioned before. Another kind of space isomerism called geometrical isomerism is found in cases where two carbon atoms are united by a double linking, as they are in ethylene. On the theory of the tetrahedal carbon atom, ethylene is represented by the following formula, in which the tetrahedra are represented as united along an edge:



C_2H_4

This formula would lead us to expect that if one hydrogen atom of each carbon were replaced by another atom, or group X, two isomers would exist having the formulæ:



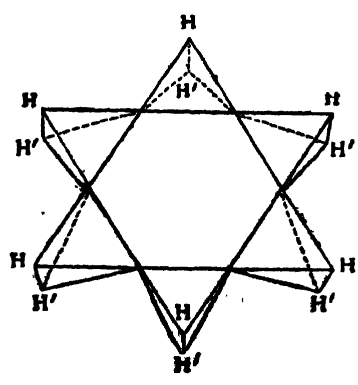
For shortness these formulæ are usually abbreviated thus:

I	II
H—C—X	H—C—X
H—C—X	X—C—H

The first example of this kind of isomerism to be discovered is that of Fumaric and Maleic Acids (*see these*):

Fumaric acid.	Maleic acid.
H—C—COOH	H—C—COOH
HOOC—C—H	H—C—COOH

To distinguish isomers of this kind, that isomer having the formula I is called the Cis or Maleinoid compound, and that having the formula II is called the Trans or Fumaroid compound. The cis-formula is assigned to maleic acid, chiefly because it readily forms an anhydride, while fumaric acid does not. Other examples of compounds showing this kind of isomerism are cinnamic acid, crotonic acid, stilbene. *See these.* Another kind of cis- and trans-isomers occurs in certain ring compounds. Let six tetrahedral carbon atoms be joined as in the figure



Now imagine a plane passing through the centres of the six tetrahedra, that is, through the carbon atoms, then the six hydrogen atoms marked H are above this plane, and the six hydrogen atoms marked H' are below it. Replace the H atom from one tetrahedron and the H' from an opposite tetrahedron by carboxyl groups. The two dicarboxylic acids so obtained are stereoisomers. The first is cis-hexahydroterephthalic acid, and the other is trans-hexahydroterephthalic acid. From the diagram it is seen that the relationship between them is similar to that between fumaric and maleic acids, the edges of the tetrahedra concerned only being separated from each other in the case of the hexahydroterephthalic acids by the intervening pairs of tetrahedra. One of these hexahydroterephthalic acids closely resembles fumaric acid and the other maleic, and that which resembles fumaric is regarded as the trans-acid and the other as the cis-acid.

Trans-Acid.	*Fumaric Acid.*
Sublimes on heating.	Sublimes on heating.
Crystallises in small prisms.	Crystallises in small prisms.
Sparingly soluble in water.	Sparingly soluble in water.
Cis-Acid.	*Maleic Acid.*
Melts at 160°.	Melts at 130°.
Crystallises in large crystals.	Crystallises in large crystals.
Much more soluble in water than the trans-acid.	Much more soluble in water than fumaric acid.

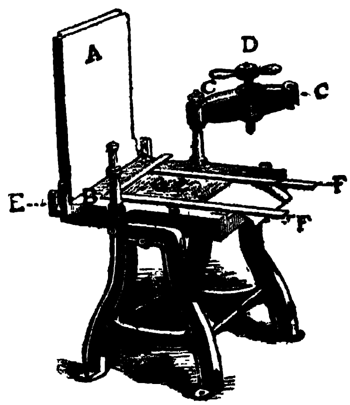
Both sets of acids are mutually convertible into each other. Unlike maleic acid, the cis-hexahydroterephthalic acid does not form an anhydride, as might be expected from the greater distance between the carboxyl groups. *See* PHTHALIC *and* TEREPHTHALIC ACIDS. For stereoisomerism of nitrogen *see* OXIMES *and* QUATERNARY AMMONIUM COMPOUNDS.

Stereometer (*Phys.*) A VOLUMENOMETER (*q.v.*)

Stereotype (*Typog.*) A cast in metal of the printing surface of a page of type. The earliest stereotypes in existence are said to have been produced about the year 1700; but as they were formed, by soldering the bottoms of types together with some metal substance, there is a doubt as to their right to the appellation. Not only was re-composition necessary when duplicates were required, but the type was put out of use for other purposes. The process proper was first practised by William Ged, a goldsmith of Edinburgh, about the year 1725, under circumstances of great difficulty, the operative printers of the time being opposed to the innovation. The secret of his methods is not known, and was lost after the death of his sons. In 1801 a patent was taken out for producing stereotypes by the plaster of Paris process. Later, through the influence of Earl Stanhope, the idea was perfected, and the process was almost universal in this country until the French or *papier maché* system partially superseded it in 1850.

The PLASTER PROCESS requires a comparatively large plant, and is to some extent uncertain in its results. The forme of type, when prepared, is placed on an inclined slab fitted within a sink. A mixture of plaster of Paris and water is poured over it, and smoothed by the hand until all the interstices of the forme are filled up. The surface is then rubbed with a hard brush until the face and shoulders of the type appear, water flowing evenly over it during the process. After being allowed to dry partially, it receives a top dressing of soap and water, and is then lightly oiled by means of a soft brush. A flask, similar in form to a chase with bevelled edges, is then placed over the forme, and plaster of Paris mixed with water to the consistency of thick cream is poured on until the chase is full. It is then beaten and rolled until the mixture is level with the edges of the chase. When properly set, this is lifted from the forme, the mould is cut out of the chase, trimmed, and put into a baking oven. It is afterwards placed face downwards in the casting box; a lid with openings at each of the corners is placed on top, fastened with a screw, and immersed in a pot of molten metal. When the box is filled, it is withdrawn and cooled. The lid is then removed, the plates knocked out, relieved of the plaster, and trimmed.

The PAPER PROCESS consists of four parts: *i.e.* the composition of the flong (*q.v.*), the preparation of the matrix, the casting of the plate, and the finishing process. The pages of type are prepared by having metal clumps of the same height placed round their outer edges. The flong when made is laid on the type, tissue downwards, and covered with a damp linen cloth. It is then beaten with a hard flat brush until the form of the type is noticeable. A thick piece of coarse paper is next pasted on, and the beating process repeated. The forme, with the mould or matrix in position, is then placed on the hollow bed or steam box of a drying press, covered with a thick blanket, and pushed beneath the platen of the press, which is screwed down. After remaining in this position for ten or fifteen minutes, the mould is removed, trimmed, furnished at one end with a strip of brown paper, and placed on the steam chamber of the press, where it remains until thoroughly hardened. Weights are placed along the edges of the mould to keep it perfectly flat. After the face has been dusted with fine French chalk, it is transferred to the casting box, which consists of two flat iron surfaces, the top one (A) serving as a lid. Both are loosely hinged together at the bottom (E), so that plates of different thicknesses may be cast as necessary. The two surfaces of the box are held firmly in position by a swinging bar (CC), which clamps them together by means of a centre screw (D). The mould (G) is laid on the lower plate (BB), with the strip of paper already referred to lying loose at the top when the box is tilted to a vertical position, thus forming a lip to guide the molten metal in its course over the face of the mould between the two flat surfaces. Lying along the edges of the mould are gauges (FF), which determine the thickness of the plate being cast.



STEREO CASTING BOX WITH UPPER SURFACE RAISED AND MOULD IN POSITION.

Several plates may be produced from the same mould A few seconds after the metal has been poured, the box is returned to its horizontal position, the screw loosened, and the upper plate or lid is raised. The plate can then be removed for trimming and finishing. The tang, or piece of superfluous metal, is sawn off, the edges are roughly trimmed, and the backs planed to ensure all plates being of uniform height. Open spaces are chiselled or chipped out, to prevent any

but the necessary parts printing on the paper, and the edges are bevelled. The plates are then ready for placing or fixing on beds or mounts, to render them uniform in height with ordinary type. The processes described refer particularly to stereotypes for flat bed printing. For rotary printing the matrix or mould is placed in a box curved to suit the cylinder of the special class of printing machine, the plates, when cast, being practically semicircular in form. There are also other systems, in which specially prepared flongs are used in a dry state.

Sterilisation (*Biology*). (1) In general terms, the destruction of the power of reproduction possessed by a living organism. (2) The destruction of organisms, especially bacteria (*q.v.*) and their spores.

Stern Tube (*Eng.*) The tube in which the end of the shaft of a screw propeller is carried through the stern of a ship.

Stern Wheel Steamers (*Eng.*) *See* AMERICAN RIVER STEAMERS.

Sterro Metal (*Met.*) A form of brass, with which 4 to 5 per cent. of iron is alloyed: it is remarkable for its strength, and was used for ordnance in Austria.

Stet (*Typog.*) *See* PRESS CORRECTIONS.

Stevenson's Screen (*Meteorol.*) *See* THERMOMETER SCREEN.

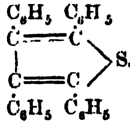
Stibnite (*Min.*) Sulphide of antimony, Sb_2S_3; antimony = 71·8, sulphur = 28·2 per cent. Orthorhombic in long crystals striated longitudinally. Colour steely grey. It is the most important ore of antimony. It is used, along with Galena, in the East to darken the under surface of the eyelids. From Cornwall, Ayrshire, Hungary, Borneo, but chiefly now from Japan, whence come fine crystals.

Sticker (*Music*). A thin rigid piece of wood used in the mechanism of the organ for pushing up certain parts. It is held in position by a wire inserted at each end through holes in the levers. *See* ORGAN, p. 439. *Cf.* TRACKER.

Stiff Leaf Foliage (*Architect.*) The conventional foliage used in Early English (*q.v.*) architecture, particularly that used in the capitals.

Stigmatic Lens (*Light*). If light diverging from a point is exactly focussed at a second point by a lens, then the lens is truly STIGMATIC. This term, though convenient, is rarely used.

Stilbene (*Chem.*) $\begin{matrix} CHC_6H_5 \\ \| \\ CHC_6H_5 \end{matrix}$ (Also called symmetrical diphenylethylene and toluylene.) Stilbene and many of its derivatives can exist in two stereo-isomeric forms, $\begin{matrix} H—C—C_6H_5 \\ \| \\ C_6H_5—C—H \end{matrix}$ and $\begin{matrix} H—C—C_6H_5 \\ \| \\ H—C—C_6H_5 \end{matrix}$ Ordinary Stilbene has probably the latter formula: it is a white solid crystallising in large monoclinic plates; melts at 124°; boils at 306°; sparingly soluble in cold alcohol, much more soluble in hot; soluble in ether and benzene; distils in steam. Its vapour passed through a redhot tube gives anthracene and toluene. On reduction by heating with hydriodic acid it gives dibenzyl, $\begin{matrix} CH_2.C_6H_5 \\ | \\ CH_2.C_6H_5 \end{matrix}$. With bromine it gives a dibromide. On prolonged heating with sulphur it gives tetraphenylthiophene,



S. Stilbene is obtained (1) by heating benzaldehyde or benzalchloride with sodium,

$$2C_6H_5CHCl_2 + 4Na = \begin{matrix} C_6H_5.CH \\ \| \\ C_6H_5\ CH \end{matrix} + 4NaCl.$$

(2) By heating phenyl fumarate,

$C_6H_5OOC.C.H$ $C_6H_5.C.H$

$H.\ddot{C}.COOC_6H_5$

Phenyl cinnamate.

(3) By heating β-trithiobenzaldehyde (obtained by passing hydrogen sulphide into a mixture of benzaldehyde and alcoholic hydrochloric acid) with copper. A few stilbene derivatives are dyes, but they are not obtained directly from stilbene.

Stilbite (*Min.*) A hydrous calcium aluminium silicate, $6H_2O, (Na_2Ca)O, Al_2O_3.6SiO_2$. Monosymmetric, in complex fourlings appearing as one crystal. Colour white, or rarely red. Pearly lustre. Dumbarton and Stirlingshire in Scotland; the Giants' Causeway; Faroë Island; India, etc.

Still Life (*Art*). A picture representing flowers, fruit, furniture, and inanimate objects generally. The Dutch School are famous for their pictures of STILL LIFE.

Stipple, Stippled (*Engrav.*) *See* ENGRAVING AND ETCHING, p. 201.

—— (*Paint.*) A method of painting in which effect is obtained by means of series of dots instead of by strokes or flat tints.

Stippler (*Dec.*) *See* PAINTERS' BRUSHES.

Stirrup (*Eng.*) The name applied to a piece of metal in the form of a loop resembling a stirrup, sometimes used in mechanism.

Stitching (*Bind.*) The term used for the method of sewing a pamphlet (or pamphlet and cover) when it consists of a single section or sheet. The sheet is opened out and sewn through the middle, the thread being cut and the ends tied together in the centre. *See* WIRE STITCHING.

Stoa (*Architect.*) A Greek term usually employed to denote a portico (*q.v.*) The Greek portico was often detached and of considerable extent. It afforded shelter while walking.

Stock (*Archæol.*) (1) The portion of a tally (generally a notched stick) which a creditor retained as evidence of the king's debt. The counterstock was retained in the Exchequer. (2) A band of leather or other stiff material, sometimes covered with a soft fabric, worn in place of a cravat.

—— (*Eng.*) (1) A general term for part of a machine or device which supports or contains an operating part or a part on which work is actually performed, *e.g.* the support of an anvil. *See* HEAD STOCK (*Eng.*) *and* STOCKS AND DIES. (2) The mass of heated coal not yet ignited surrounding the hot part of a smith's fire.

—— (*Her.*) A bearing consisting of the stump of a tree cut off square at the top and eradicated at the roots, the main roots being shown.

Stockingette Cloth (*Textile Manufac.*) May be either knitting which is the original stockingette, or woven in the ordinary way, what is termed a "stockingette" weave being used.

Stock Rail (*Eng.*) The fixed rail which is fitted at points (*q.v.*) in a railway, as distinguished from the hinged rail or point proper. *See under* RAILWAYS.

Stocks. Bricks burnt in a clamp. *See* BRICKS.

—— (*Archæol.*) A device for punishing petty offenders. It consisted of a heavy wooden frame with movable planks placed horizontally on edge, the latter being pierced with holes for confining the legs or arms or both.

—— (*Civil Eng.*) The massive timbers on which a ship rests while being built.

—— (*Woollen Manufac.*) An old form of fulling or felting (*q.v.*) Usually the machine consists of a pair of stocks, but they have also been made with only one stock foot, and with three. In the older form of the machine the stocks are allowed to fall on the material by gravity; in the newer form they are controlled by crank gearing, and the length of the traverse can be diminished or lengthened as required.

Stocks and Dies (*Eng., etc.*) Tools used for cutting external or "male" threads. The die consists essentially of a hardened steel nut, which is usually divided into two parts, the ends of the threads where they are cut across serving as cutting edges for producing the new thread which is to be cut. The STOCK is a suitable holder for the dies, commonly with a screw by means of which the distance apart of the two halves of the nut may be adjusted, and two straight handles by means of which it is turned in order to produce the thread. When commencing to cut a thread the two halves of the die are separated to such a distance that they will just allow the blank on which the thread is to be cut to enter; the stock is then turned and the dies gradually cut a thread, which is deepened by screwing the dies closer together after each cut.

Stocks, Grey, *and* **London.** *See* BRICKS.

Stokehold (*Eng.*) A term commonly used in marine practice as the equivalent of "boiler house"; the place in which the stoking of the boilers is carried on.

Stokehole (*Eng.*) (1) A pit or other space in or from which stoking is carried on. The space allotted to the stokers or firemen in a steamship for supplying fuel to the furnaces is usually sermed a stokehold (*q.v.*) (2) A hole in a reverberatory furnace for introduring a rabble (*q.v.*) or other tool.

Stoking (*Eng.*) Putting fuel into a furnace, etc., removing clinkers, and generally attending to the fire.

Stola (*Archæol.*) The outer garment worn by the Roman matron. *Cf.* PALLA.

Stole (*Cost.*) A narrow band, fringed at the ends, worn by the clergy over the shoulders.

Stomata (*Botany*). Minute openings in the epidermis of leaves and other green parts of a plant concerned in gaseous interchange between the tissues and the atmosphere. Special "guard cells" surround an opening which leads to the intercellular spaces of the leaf.

Stone Age. The Prehistoric Period during which Early Man shaped and used implements of stone. It is usually regarded as divisible into two periods:—an Earlier or Palæolithic, during which rudely shaped and unpolished stone implements were used, and a Later or Neolithic, at which time a more carefully finished type was used. The Earlier Stone Age may have lasted all through the Glacial Period, while the Later is certainly posterior in date to the Age of Snow.

Stoneware. A species of hard glazed pottery composed of silicious clay; or of clay and flint which has been ground and calcined, mixed in proper proportions. The glaze is effected by means of common salt, which is thrown into the furnace in which the ware is baked. *See* POTTERY.

Stool (*Build.*) The small surface worked on a stone sill to form a butt joint for the mullion.

Stoop. (1) A flagon or large cup for holding liquor. (2) A low platform or a portico in front of a house.

Stop. A very general term for a piece of metal or other material used to fill up some cavity, or to limit or check the motion of some piece of mechanism.

—— (*Build.*) The termination of a chamfer when it is not worked the whole length of a stone.

—— (*Carp. and Join., etc.*) (1) A projecting piece of wood or metal, used to keep a piece of wood from sliding along the bench when being planed. (2) One of the pieces of wood fastened to the frame of a door to form a recess into which the door shuts.

—— (*Music*). (1) A set of pipes in an organ. (2) Each knob by which the organist puts into action the various sliders. Properly known as a Draw stop. *See* MUSICAL INSTRUMENTS, p. 439.

Stop Cock (*Build.*) A cock or tap fixed near the main pipe to turn on or shut off the supply of gas or water in a house.

—— (*Eng.*) A term often applied to any cock or tap.

Stope (*Mining*). The parts of a mine between two levels, from which the ore is obtained in workings usually having the form of steps. OVERHAND STOPING consists in working from the under side, when the steps have the appearance of the under side of a staircase; in UNDERHAND STOPING the men work while actually standing on the steps.

Stoping (*Mining*). The excavation of minerals in steps, either above or below a certain level. OVERHAND STOPING: Excavating in an upward direction, the usual method. UNDERHAND STOPING: Excavating in a downward direction. *See also* STOPE.

Stopped Pipe (*Music*). An organ pipe having the upper end closed either by a STOPPER (*q.v.*) or metal cap. A stopped pipe gives a sound an octave lower than an open pipe. This is spoken of as so many feet tone; *e.g.* stopped diapason 8 ft. tone gives the same pitch as the open diapason 8 ft. In the former case the lowest pipe is 4 ft. long, in the latter 8 ft. long.

Stopper (*Glass Manufac.*) A slab of fireclay used for temporarily stopping up the mouth of the pot (*q.v.*) during founding.

—— (*Music*). The wooden plug inserted at the top of certain organ pipes, which causes the sound produced to be an octave lower than when unstopped (open).

Stoppering (*Met.*) Closing up the opening of the mould used for casting steel ingots, in order to prevent the action of the air on the fluid metal.

Stopping (*Build., Dec., etc.*) A substance, *e.g.* a mixture of size and whiting, used for filling nail-holes, shakes, cracks and flaws, etc., in the surface of work which has to present a smooth and finished appearance. *Cf.* BEAUMONTAGE.

—— (*Music*). The pressing of the fingers on the strings of stringed instruments to obtain other sounds than those given by the open strings (*q.v.*) When two notes are produced at once in this way, *i.e.* by stopping two strings, it is termed DOUBLE STOPPING.

Stopping Knife (*Dec.*) A knife used by painters for stopping nail-holes, etc., with putty.

Stopping Off (*Foundry*). Closing or filling up part of a mould in order to modify the size or shape of the casting.

Stopping Out (*Etching*). Covering with lamp-black, or other acid-resisting substance, certain portions of a plate which is being etched in order to prevent further etching of those parts. *See* ENGRAVING AND ETCHING *and* PHOTO-ENGRAVING.

Stop Valve (*Eng.*) A STOP COCK (*q.v.*)

Stop Watch (*Clocks and Watches*). A watch whose mechanism can be stopped or started at will by pressing a projecting stud. The most convenient type possesses separate mechanism, furnished with special indicating hands, capable of being stopped or started at any time without interference with the ordinary movement. One of these hands usually makes one complete revolution per minute, and indicates to the fifth of a second, while a second or smaller hand records the minutes completed since the watch was started.

Stop Work (*Clocks and Watches*). The arrangement limiting the amount of winding up permitted to the weight or mainspring.

Storage Battery (*Elect.*) A set of storage cells or accumulators (*q.v.*).

Storage Cell (*Elect.*) An ACCUMULATOR (*q.v.*).

Storm (*Meteorol.*) A violent commotion of the atmosphere, occurring in all climates and differing from other atmospheric disturbances in its destructive power and the extent over which it spreads.

Storm Beach (*Geol.*) The maritime zone along which the direct effects of the sea are manifested only during heavy gales. In general terms it may be said to range along the shore to a short distance inland from high-water mark.

Storm, Magnetic. Irregular or exceptional variations in the earth's magnetic element.

Storm Warnings (*Meteorol.*) Notices, telegraphed or published, predicting the approach of storms from the behaviour of the barometer or other instruments.

Storm Waves (*Meteorol.*) Exceptionally high waves occasioned by low atmospheric pressure during storms. Rendered more severe when occurring at high water and violent wind.

Story Rod (*Carp. and Join.*) A long stick used for setting out stairs, *e.g.* for measuring the vertical height from floor to floor.

Stoup. *See* STOOP.

Stourbridge Clay. A fireclay occurring in the Coal Measures at Stourbridge and elsewhere; it contains but little iron and very little lime or alkali. As it is very refractory, and can be heated to very high temperatures without melting or becoming pasty, it is much used for firebricks, crucibles, etc.

Stove. (1) A term loosely applied both to open fireplaces and to stoves proper, which are closed chambers. *See* STOVES. (2) A form of oven used for drying, enamelling, and many other purposes.

Stoves (*Hygiene*). Are commonly made of cast iron, the smoke and products of combustion escaping by an iron flue to the chimney or outer air, while the main portion of the heat radiates in all directions round the stove. This is a more economical but less healthy mode of heating than by an open fireplace, the ventilating power being less. There are three chief objections to the use of stoves: (1) They render the air hot and dry; this may be in a measure obviated by placing a vessel of water on the stove. (2) The escape of carbon monoxide through the walls of the stove; this objection may be overcome by lining the stove with firebrick and casing it with tiles, as is done on the Continent. (3) The bad smell sometimes caused by the decomposition of organic matters present in the air, due to their contact with the heated surface of the stoves.

Stove Screw (*Build.*) A screw with the thread cut close up to the head, used in fitting together the parts of stoves.

Straight Arch (*Build.*) See CAMBER ARCH.

Straight Edge (*Eng., Carp., etc.*) A flat rod of wood or metal; the edge is used for testing the accuracy of straight lines or plane surfaces.

Straight Pass (*Textile Manufac.*) *See* ENTERING.

Strain (*Phys., Eng., etc.*) A change in the dimensions or form of a body, produced by the action of forces termed STRESSES. Various kinds of strains are defined under ELASTICITY (*q.v.*)

Strainer (*Eng.*) A perforated cover attached to the end of the suction pipe of a pump, to prevent the entry of pieces of material which would obstruct the valves.

Straining (*Leather Manufac.*) The stretching or straining of skins in their wet state by nailing them out on frames and drying them in this strained condition, thus preventing contraction.

Straining Beam (*Carp. and Join.*) The horizontal timber that extends between the heads of the queen posts. *See* ROOFS.

Strain Slip Cleavage (*Geol.*) A structure developed in certain rocks by dynamic metamorphism. Intense lateral pressure, such as that exerted during the upheaval of great mountain masses, throws the finer laminæ of a stratified rock into minute puckers, which fracture at their crests and troughs, and eventually slip, or become faulted, on a very minute scale, along parallel planes which lie nearly at right angles to the direction of the pressure. A rock so affected is said to be sheared. If new minerals are developed along the planes of slip the rock becomes a SCHIST.

Straits Tin (*Met.*) Tin from the Straits Settlements—*e.g.* the Malay Peninsula, the islands of Banca and Bilitong, etc.; usually considered one of the very best varieties obtainable.

Strait Work (*Mining*). *See under* MINING.

Strake (*Mining*). A sloping board used in sorting gold ore.

Stramonium (*Botany*). The dried leaves and seeds of *Datura stramonium* (order, *Solanaceæ*) are used in the preparation of the drug.

Strand. (1) A number of single threads of some material (yarn, etc.) twisted together and forming one of the principal parts of a rope. (2) A single thready filament or small cord.

Stranded Conductor (*Elect. Eng.*) A conductor formed of a number of fine wires grouped into strands; used when flexibility is required.

Strap (*Eng.*) (1) A belt (*q.v.*) (2) A strip of metal specially shaped for holding together and strengthening parts of a structure round which it fits, *e.g.* an eccentric strap.

Strap Bar (*Eng.*) A bar sliding through fixed supports and carrying the STRAP FORK (*q.v.*)

Strap Brake (*Eng.*) A strip of metal, firmly fixed at one end, bent over a wheel or brake drum: when drawn tight by means of a lever, so as to grip the wheel closely, it acts as a brake. Used both as a brake proper and in certain forms of DYNAMOMETER (*q.v.*)

Strap End (*Eng.*) The end of a connecting rod in which the brasses are held in place by a strap passed round them and fixed to the rod by means of a gib and cottar (*q.v.*)

Strap Fork (*Eng.*) A two-pronged fork which loosely encloses a belt, for the purpose of shifting it from one pulley to another of equal size, turning on the same axis and placed alongside the first.

Strapping Motion (*Cotton Manufac.*) *See* GOVERNING MOTION.

Strap Work (*Architect.*) An Elizabethan ornament resembling interlacing straps.

Stratus Clouds (*Meteorol.*) Are those which present a stratified or band-like form. They may be high- or low-lying clouds. *See also* CLOUDS.

Strawberry (*Botany*). The fruit of *Fragaria vesca* (*Rosaceæ*) consists of a fleshy receptacle bearing numerous minute achenes (the so-called seeds).

Strawberry Leaf (*Her.*) An ornament of conventional form resembling a strawberry leaf appears on many ancient crowns and coronets. They now appear on the coronets of dukes, marquesses, and earls. *See* CORONET.

Stray Field (*Elect. Eng.*) A magnetic field, produced by lines of force from the field magnets of a dynamo which do not pass through the armature, and which are therefore useless for the purpose of inducing an electromotive force in the armature conductors.

Streak (*Min.*) The appearance produced when a piece of a mineral is rubbed over an abrading surface harder than its own. The lustre and general appearance of the streak is often a useful guide in the identification of a mineral.

Stream Currents (*Meteorol.*) Currents produced when DRIFT CURRENTS (*q.v.*) are deflected by a coast line or other obstacle.

Stream Lines. Imaginary lines drawn in a fluid in motion, such that the direction of motion of any particle at any given instant is a tangent to the curve passing through the particle.

Stream Tin (*Min.*) Tin-stone in a state of fine division which has been washed down and deposited by rivers.

Strength of Field (*Elect.*) The strength of an electric field at a point is measured by the number of lines of force per square centimetre at that point. In air this is numerically equal to the force in dynes exerted on a unit charge placed at the same point, but this will not be true for other media, the general relation between Force (dynes) and Field (lines per sq. cent.) being, Field = K × Force, where K is the dielectric constant (or specific inductive capacity), and is arbitrarily taken as unity for air. The strength of a magnetic field is similarly defined. In air this is numerically equal to force in dynes on unit pole at the given point, but the force is not to be confused with the field, the general relation being Field = μ × Force, where μ is the permeability of the medium. This practically only differs from unity in the case of iron and a few magnetic substances.

Strength of Pole. *See* MAGNET.

Strepitoso (*Music*). In an impetuous or boisterous manner.

Stress (*Phys., Eng., etc.*) A stress, from the practical point of view, is a force which produces, or tends to produce, an alteration in the form or dimensions of a body upon which it acts. The external force is resisted by internal forces acting between the molecules of the body, and to these internal forces the term "stress" is more properly applied. *See also* ELASTICITY.

Stress Diagram. A drawing made for the purpose of calculating the different stresses in the members of a loaded structure. *See also* GRAPHIC STATICS.

Stretched String (*Sound*). Vibrating strings form an essential part of many musical instruments (*q.v.*) and certain pieces of scientific apparatus, *e.g.* a SONOMETER (*q.v.*) The frequency of vibration of a string depend on its length, its mass, and the tension applied to it. Let l be the length, m the mass per unit length, and T the tension, expressed in the corresponding units of force (*i.e.* if l is in cms., m in grams, then T must be in dynes). The frequency n (or number of vibrations per second), when the string is vibrating as a whole and therefore emitting its fundamental note, is $n = \frac{1}{2l}\sqrt{\frac{T}{m}}$. The frequencies of the over-tones (*q.v.*) will be $2n$, $3n$, etc.

Stretcher (*Build.*) (1) A brick or stone laid with the greatest length parallel to the surface of the wall. *Cf.* HEADER. (2) A tie-beam in the framing of a building.

—— (*Eng., etc.*) A strut or member of a structure which fixes two other parts a definite distance apart: *e.g.*, the horizontal member in an A-frame.

—— (*Paint.*) A frame on which a canvas intended for painting is fastened, and then stretched by means of wedges forced in at the corners, or by some other device.

Stretching Course (*Build.*) A row of bricks laid lengthwise on the face of a wall. *Cf.* STRETCHER.

Stretto (*Music*). Contracted; close. *See* FUGUE.

Striæ (*Glass Manufac.*) Markings or cords caused by variations in the temperature of the furnace. In flint glass they are chiefly due to the unequal density of the materials employed.

—— *or* **Striations** (*Elect.*) A banded appearance due to alternations of dark and bright spaces produced under certain conditions in vacuum tubes (*q.v.*)

Strickle (*Foundry*). A piece of wood or metal used to produce a surface of definite form on the sand in a moulding box. The strickle is cut to the required shape and drawn over the sand in the proper direction, which is maintained by means of suitable guides, pivots, etc.

Strickling (*Foundry*). Forming a simple mould or part of a mould by means of the STRICKLE (*q.v.*) instead of by the use of a pattern.

Strict Counterpoint (*Music*). By strict counterpoint is understood the art of combining melodies under the following restrictions: (1) Common chords and their first inversions only allowed. (2) A complete absence of discords, except the suspensions of the 4-3; 9-8; 7-6; 7-8; 5-6, and passing notes. (3) Diatonic progressions only. The study of strict counterpoint is perhaps the most essential part of a thorough musical training, as it enables the student to write in a flowing manner under very severe conditions. He is then fit to enter the much wider sphere of composition, which comprises writing and combining the five different species of counterpoint under modern conditions, using chromatic progressions, discords, and all the combinations and progressions of modern harmony. This is known as Free Counterpoint. These are also called respectively Students' Counterpoint and Composers' Counterpoint, terms which in many ways seem to be better. *See* COUNTERPOINT.

Strict Fugue (*Music*). A real FUGUE (*q.v.*)

Strigil (*Archæol.*) A scraper, fashioned variously, of metal, ivory, bone, etc., and used for scraping the skin at the bath or on other occasions.

Strike (*Build., etc.*) To lower or take down, *e.g.* a scaffold or the centre of an arch.

—— (*Geol.*) The direction of a horizontal line on the bedding plane of an inclined stratum. Otherwise: the compass bearing of the line formed by the intersection of the plane of an inclined stratum and a horizontal surface. It may best be realised by partly immersing a slate, inclined at any angle from the horizontal position, in a bowl of water; the line of contact of the water surface with the face of the slate is the direction of the strike. The definition of "strike" given in most text books is incorrect.

—— (*Typefounding*). The term applied to the matrix in which a type is cast. *See* TYPEFOUNDING.

Striker (*Print.*) A lever for shifting the driving belt of a machine to stop or start it.

Striking an Arc (*Elect.*) Starting an electric arc by bringing the carbons into contact and immediately separating them.

Striking a Screw (*Eng., etc.*) Commencing the cutting of a screw-thread with a chaser (*q.v.*)

Striking Distance (*Elect.*) The distance between two conductors, across which a spark will pass with a given difference of potential.

Striking Knife (*Carp., etc.*) A knife or scriber used in striking out or marking timber ready for cutting to shape.

Striking Mechanism (*Elect. Eng.*) The mechanism, usually worked by the current, by which the striking of an arc (*q.v.*) is effected

Striking Out (*Carp., Eng., etc.*) Drawing a piece of work, especially drawing it full size in the workshop, or actually marking out lines, etc., on the material itself.

Striking Plate (*Carp. and Join.*) The plate fixed to the jamb of a door frame for the bolt of the lock to shoot into.

Striking Reed (*Music*). *See* REED.

Striking Up, *or* Striking (*Foundry*). STRICKLING (*q.v.*)

String (*Mech.*) In theoretical mechanics the term string is applied to an imaginary body which is capable of transmitting a force only in the direction of its own length, *i.e.* which is perfectly flexible.

—— (*Mining*). A thin vein of ore.

—— (*Phys.*) *See* STRETCHED STRING.

—— (*Woollen and Worsted Manufac.*) A length of 10 ft. The chain or warp is frequently defined in strings.

String Course (*Architect.*) A horizontal moulding or a coloured or projecting band on the face of a building.

Stringendo (*Music*). Hurrying the time with excitement.

String Quartet (*Music*). A composition for four stringed instruments, generally first and second violins, viola, and violoncello.

Strings (*Carp. and Join.*) The inclined boards supporting the ends of steps. *See* STAIRCASE.

Strip *or* Taper (*Foundry*). *See* TAPER.

Strippers *or* Workers (*Textile Manufac.*) *See* CARDING ENGINE.

Stripping (*Eng.*) Tearing or breaking off the thread of a screw or the teeth of gear wheels through improper usage.

—— (*Lace Manufac.*) A simple method of removing the unused cotton that remains upon the brass bobbins, when time is an object or the material not of sufficient value to pay the expense of "jacking off." *See* JACK OFF.

Stripping Film (*Photo.*) A sensitive gelatine film which is mounted on paper or other non-transparent support; after the film has been developed and fixed, it is removed or stripped from the support, for printing.

Stripping Plate (*Met.*) A bevel edged template fitted tangentially to the rolls of a mill to coincide with the grooves, thus clearing the bars from the bottom roll, and preventing them "collaring" or wrapping round the bottom roll. It is fitted at the back of the rolls in almost the same position as the foreplate (*q.v.*) at the front.

Stroboscope (*Phys.*) An instrument for observing a body which is executing rapid vibrations. The body is viewed through a small opening in an opaque screen which is moving in the same plane as itself; if the rate of motion of the screen be the same as that of the vibrating body, the latter will appear at rest when viewed through the opening. For example, the screen may be mounted on the tip of the prong of a tuning fork; then if it be set in vibration, and another fork, vibrating in the same plane, with the same frequency, be observed through the slit, the prongs of the second fork will appear at rest; if the frequencies of the forks differ by a small amount, then the prong of the second fork will appear to move slowly to and fro.

Stroke (*Eng.*) The distance moved through by the piston of an engine, plunger of a pump, or other reciprocating mechanism.

Stroker (*Print.*) A piece of wood with a smooth metal face, used for stroking the sheets of paper towards the grippers of the printing machine.

Strong Sand (*Foundry*). Moulding sand rendered adhesive by the admixture of loam, etc.

Strontia (*Chem.*) Strontium oxide or hydroxide.

Strontianite (*Min.*) Strontium carbonate, $SrCO_3$; strontia = 70·2, carbon dioxide = 29·8 per cent. Orthorhombic, usually in divergently fibrous masses. Pale apple green, greyish or white. The principal source of strontium compounds. From Strontian in Argyleshire, Yorkshire, the Harz, New York State, etc.

Strontium (*Min.*) The element does not occur native. Only two minerals containing it are at all abundant, the carbonate Strontianite (*q.v.*) and the sulphate Celestine (*q.v.*)

Strontium and its Compounds (*Chem.*) STRONTIUM (Sr, atomic weight 87·6) belongs to the same group of elements as calcium and barium; like them it is a white metal, which decomposes water at the ordinary temperature, forming the hydroxide and liberating hydrogen; like them, also, it occurs as carbonate (Strontianite) and sulphate (Celestine); it is obtained pure in the same way as barium. COMPOUNDS: STRONTIUM OXIDE, SrO, resembles quicklime in appearance; melts about 3000°; more soluble in water than quicklime, giving a strongly alkaline solution of strontium hydroxide, $Sr(OH)_2$. The oxide is obtained by heating the nitrate or by very strongly heating the carbonate; the hydroxide is obtained by adding water to the oxide or by heating the carbonate in a current of steam. The HYDROXIDE is a white solid which crystallises from hot water, as $Sr(OH)_2 8H_2O$; it combines with cane sugar to form a saccharate, which is insoluble in water, and on this account strontium hydroxide is used in recovering cane sugar (*q.v.*) from the uncrystallisable molasses. STRONTIUM CHLORIDE, $SrCl_2$, crystallises with six molecules of water, and is soluble in water and alcohol; the anhydrous salt melts at 832°; it is obtained by dissolving the carbonate or hydroxide in hydrochloric acid and crystallising. STRONTIUM NITRATE, $Sr(NO_3)_2$, crystallises in anhydrous octahedra; very soluble in water; obtained by dissolving the carbonate in dilute nitric acid and evaporating. It is much used in making red fire. The carbonate and sulphate resemble the corresponding barium salts, but the sulphate is more soluble in water (·0145 gram $SrSO_4$ in 100 cc. water at 20°; ·00025 gram $BaSO_4$ in 100 cc. at 18°).

Struck Core (*Foundry*). *See* CORE.

Structure (*Eng.*, *etc.*) An assemblage of related parts attached to one another in a definite manner. In practice the term is usually, though not always, restricted to buildings, bridges, roofs, etc., as distinguished from machines.

Strut (*Build.*, *Eng.*, *etc.*) A member of a structure which is in compression, *i.e.* the forces applied at the two ends act towards each other.

Strychnine (*Botany*). The alkaloid obtained from the disclike seeds (Nux Vomica) of *Strychnos nux vomica* (order, *Loganiaceæ*).

—— (*Chem.*) $C_{21}H_{22}N_2O_2$. Forms large white rhombic prisms; melts about 266°; distils at 270° under a pressure of 5 mm.; slightly soluble in water (100 parts water dissolve ·025 parts at 14·5°), more soluble in alcohol (100 parts absolute dissolve ·302 at 8·25°): chloroform is the best solvent (1 part in 6·9); its solutions are lævorotatory. It has an extremely bitter taste—1 part in 70,000 of water is distinctly perceptible. Strychnine is intensely poisonous. The fatal dose is not known; a little over a grain has proved fatal, while larger doses have not. Medicinal dose, $\frac{1}{30}$ to $\frac{1}{16}$ grain; it is used in making many vermin killers, in which it is mixed with starch and a colouring matter such as ultramarine. In medicine it is used as a tonic on account of its stimulating action on various centres. In poisonous doses it causes violent and frequent convulsions, affecting nearly all the muscles; apomorphine and chloral are used as antidotes. Strychnine is a strong monacid base; its commoner salts are the sulphate, hydrochloride, nitrate, and acetate, all of which are more soluble in water than the alkaloid. In pure chemistry strychnine is used to resolve racemic mixtures or compounds into their optically active components. *See* STEREOISOMERISM *and* DEXTROSE. It occurs in nux vomica (dried ripe seeds) to the extent of from 0·9 to 1·9 per cent., and in St. Ignatius bean to 1·5 per cent.; brucine occurs with it in these. To obtain it the nuts are softened by exposure to steam, powdered, and extracted with somewhat diluted alcohol containing a little sulphuric acid; the filtered extract is neutralised with lime, and the clear solution evaporated; the residue is extracted with dilute acid, the extract filtered and precipitated with ammonia; the precipitate contains brucine, from which it can be freed by crystallisation from alcohol, in which brucine is the more soluble; or the alkaloids are dissolved in acetic acid, the solution evaporated on the water bath, when the strychnine acetate is decomposed, and water only dissolves brucine acetate from the residue. The constitution of strychnine is unknown; but it is a tertiary base, as it unites with alkyl iodides, and it appears to contain a benzene ring condensed with a nitrogen ring, the nature of which is not settled, for it yields halogen substitution products, of which bromstrychnine yields picric acid by the action of fuming nitric acid; also when distilled with caustic potash, quinoline and indole are among the products, while when distilled with zinc dust, carbazole is obtained. Strychnine gives the usual alkaloid reactions; the best test for it is the addition of strong sulphuric acid and a little dichromate of potash, when a transient violet coloration is observed.

Stuart's Granolith. *See* ARTIFICIAL STONE.

Stub Tenon (*Carp. and Join.*) A short tenon which does not pass right through the piece which contains the mortice.

Stucco (*Build.*) (1) Plaster of fine quality made from powdered white marble, gypsum, sand, and water: used to form the surface of walls and for ornament in relief. (2) Generally any plaster or cement used to form the external surface of a building, often finished off to imitate masonry.

Stück (*Music*). The German term for piece, as *Concertstück*, a concert piece.

Stuck Moulding (*Carp. and Join.*) Moulding which is worked on the solid wood, as distinguished from moulding which is formed on a separate piece of wood and afterwards attached to the main part of the work.

Stud (*Build.*) A post or upright support. One of the scantlings to which the match boards are nailed in a frame building.

Stud (*Eng.*) (1) A short projecting pin or boss. (2) A screw, having no fixed head, which is screwed into a tapped hole in some larger object, the nut being screwed on to the projecting end. (3) The transverse piece of cast iron in the link of a cable chain for the purpose of keeping the sides apart.

—— (*Watches and Clocks*). The fixed piece to which the outer end of a balance spring is attached. Any fixed piece forming a centre of motion for movable pieces, *e.g.* the various studs on which the different parts of the striking mechanism of a clock turn. *See also* STOP WATCH.

Stud Block (*Eng.*) A piece of metal having a tapped hole which does not pass right through the block. It is used for screwing studs (*q.v.*) into their holes.

Studded Chain (*Eng.*) A chain with STAYED LINKS (*q.v.*)

Studio (*Art*). The workroom of an artist; an atelier.

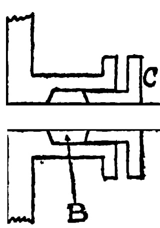
Stud Wheel (*Eng.*) A wheel revolving on a short fixed axle projecting from the framework of a machine; especially applied to a wheel used in screw-cutting lathes to connect the wheel on the mandrel with that on the leading screw.

Stuff. (1) A general term for material. (2) Woven material, especially a woollen fabric. (3) In joinery the term is applied to wood.

Stuff Chest (*Paper Manufac.*) A cylindrical tank, containing the stock of beaten pulp ready for moulding in the machine.

Stuffing (*Leather Manufac.*) Impregnating leather with grease. The two terms "stuffing" and "currying" differ only in degree, stuffing meaning a heavy currying. The term "currying" is used when only a light oiling is applied. *See* CURRYING.

Stuffing Box (*Eng.*) The device by which a steam-tight joint is obtained where a piston rod enters a cylinder. The rod A passes through a hole in the cylinder cover, which fits the rod smoothly; this hole widens out into a cylindrical chamber B of larger diameter than the rod, and soft packing of asbestos, etc., is placed in it so as to surround the rod. The end of the recess is filled by a short tube or sleeve C, termed a GLAND; this fits into the recess, and is bored out to such a size that the piston rod can move easily through it. The gland is held in place by bolts, and compresses the packing so as to fill the cavity round the rod, thereby making a steam-tight joint in which friction is reduced to a minimum.



STUFFING BOX.

Style (*Archæol., etc.*) (1) An instrument of bone, metal, or ivory, with one end pointed and the other end blunt, the pointed end being employed for inscribing on wax-covered tablets, and the other end for erasing and for smoothing the surface of the wax. (2) A pointed tool used in engraving, etc. (3) The marking point of a telegraph receiver, etc.

Style of the House (*Typog.*) A code framed for the guidance of compositors and others respecting punctuation, capitalisation, divisions, spacing, etc.

Styles (*Carp. and Join.*) The outside vertical members of a piece of framed work, such as a door.

Stylobate (*Architect.*) The substructure supporting a colonnade. It can be either in the form of a

STYLOBATE, TEMPLE OF CERES, PÆSTUM.

podium (*q.v.*) or a series of steps. The stylobate of the Parthenon consists of three steps.

Styrolene (*Chem.*) $\begin{array}{l}CHC_6H_5\\ \|\\ CH_2\end{array}$ (*also called* PHENYL-ETHYLENE STYRENE). A colourless liquid; boils at 144°; aromatic smell; soluble in alcohol and ether; polymerises on keeping, especially in light; it occurs in the balsam Storax (1 to 5 per cent.) and in coal tar. It can be obtained by distilling storax with water; by decomposing β-bromhydrocinnamic acid (from cinnamic acid and hydrobromic acid) with caustic soda—

$$\begin{array}{l}CHBr\,.\,C_6H_5\\ |\\ CH_2\,.\,COOH\end{array} = \begin{array}{l}CHC_6H_5\\ \|\\ CH_2\end{array} + HBr + CO_2$$

or by condensing benzene and acetylene with aluminium chloride.

Suabe Flute (*Music*). An organ stop of wood, having an inverted mouth. Its tone is of a somewhat sorrowful character. It seldom goes below tenor C, but is grooved into a stopped diapason.

Suave (*Music*). Agreeable; sweet.

Subaerial Denudation (*Geol.*) *See* DENUDATION.

Sub-bass (*Music*). A pedal stop on organs of 32 ft. tone. The term is, however, sometimes used in the same sense as, or instead of, bourdon, and then is of 16 ft. tone.

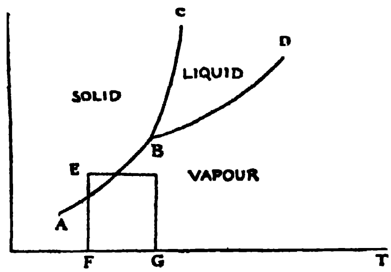
Subdominant (*Music*). The *Under-dominant.* The technical name of the fourth note of a scale, so called from its being in the same position below the tonic as the dominant is above.

Subito (*Music*). Suddenly; quickly.

Subject (*Music*). (1) The principal phrase, or sets of phrases, constituting the complete theme of a movement. (2) The opening phrase of a fugue. *Cf.* ANSWER.

Sublimation (*Chem.*) Strictly speaking, is the change of a solid to a gas without previous melting, and the change of the gas back to the solid without liquefaction. But the term is often applied to a substance which melts on heating, and then boils and gives off a gas which condenses to a solid without liquefaction. Any substance will come under the strict definition which has a sufficient vapour pressure at a temperature below its melting point. Thus camphor melts at 180°, but it sublimes at the ordinary temperature; this is due to the fact that camphor has a considerable vapour pressure at, say, 15°, so that if a piece of camphor is placed under a bell jar at this temperature, the space is filled with vapour of camphor, and part of it condenses again on the colder sides of the jar. Again, when sulphur is purified by distilling it in iron vessels and passing

the vapour into a large brick chamber, the vapour solidifies at first without liquefying; this is not a strict sublimation, and the sulphur solidifies in this case because of the lowering of its temperature by expansion against the pressure of the air and the lowering of its vapour pressure owing to the vapour mixing with air. In the diagram let the horizontal line represent temperatures, the vertical line pressures, the curve AB the vapour pressure of the solid, the curve BD the vapour pressure of the liquid, and the curve BC the effect of pressure on the melting point;



then it is seen that at any pressure below that at the triple point B a solid can pass into the state of vapour without liquefaction, and vapour to solid without liquefaction. Select a pressure FE, and heat the solid in a vessel at temperature G, and let the vessel communicate with another at temperature F; then the solid will sublime without melting. Ice melts at 0° very nearly, and the value of B is about 4·6 mm; so that if ice is placed in a vessel the pressure inside which is kept, say, at 3 mm. and the temperature 0°, the ice would slowly sublime, and might be condensed in a second vessel at the same pressure as the first, but at a lower temperature. Many substances are purified by subliming them, as, for example, iodine, arsenious oxide, benzoic acid, ammonium chloride.

Submarine Cable (*Elect.*) A conductor or system of conductors electrically insulated and provided with a strong covering, proof against the action of sea water. Used chiefly for telegraphic communication.

Submediant (*Music*). The *Under-mediant.* The technical name of the sixth note of a scale; so called from its being in the same position, *i.e.* midway, between tonic and the subdominant in descending, as the mediant is between tonic and dominant in ascending.

Sub-octave (*Music*). A coupler in an organ which causes the note an octave below the note played to fall.

Substitution (*Chem.*) The replacement of one or more atoms in the molecule of a compound by one or more different atoms or groups of atoms, the valency of which is equal to that of the atom or atoms replaced. The product of such a change is called a substitution product. As an example of substitution may be given the action of chlorine on acetic acid:

$\begin{array}{l}CH_3\\ \mid\\ COOH\end{array}$	$\begin{array}{l}CH_2Cl\\ \mid\\ COOH\end{array}$	$\begin{array}{l}CHCl_2\\ \mid\\ COOH\end{array}$	$\begin{array}{l}CCl_3\\ \mid\\ COOH\end{array}$
Acetic Acid.	Monochloracetic Acid.	Dichloracetic Acid.	Trichloracetic Acid.

A great part of the reactions of organic chemistry are substitution reactions, and organic chemistry has been defined as the chemistry of the hydrocarbons and their derivatives, that is, their substitution products. The substituent, as the entering group is called, always changes the properties of the original compound; thus in the example above the strength of the acid increases with the number of chlorine atoms. In some classes of compounds rules are known relating to the place where a substituent will enter; thus in the fatty acids halogens enter the group next to the carboxyl group. In benzene, if a hydrogen atom is substituted by one of the following, Cl, Br, I, CH_3, and other alkyls, CH_2Cl, CH_2CN, CH_2COOH, OH, OCH_3, NH_2, $NHCOCH_3$, $-N=N-$, C_6H_5, a new substituent enters the ortho- or para-position, and little or no meta-derivative is formed; but if a hydrogen is substituted by one of the following, NO_2, SO_2OH, CHO, COOH, $COCH_3$, CN, a new substituent will enter the meta-position, and little or no ortho- and para-derivative will be formed.

Subtonic (*Music*). The Leading Note (*q.v.*)

Succentor (*Music*). The deputy of the Precentor (*q.v.*)

Succinic Acid (*Chem.*)

$$\begin{array}{l}CH_2COOH\end{array}$$

White monoclinic prisms; melts at 185°; boils at 235°, with decomposition into anhydride,

$$\left.\begin{array}{l}CH_2.CO\\ \mid\\ CH_2.CO\end{array}\right\rangle O,$$

and water; soluble in water and alcohol; sparingly soluble in ether. It occurs in amber, many resins, in turpentine, in the oxidation of fats with nitric acid, in the alcoholic fermentation of sugar, and in urine. It can be prepared by the distillation of amber; by fermentation of ammonium tartrate in presence of small quantities of potassium phosphate, magnesium sulphate, and calcium carbonate to serve as food for the ferment. The fermentation starts on exposure to air, and with 2,000 grs. of tartaric acid it is complete in about seven weeks at 25° to 30°. The liquid is concentrated, cleared by albumen, precipitated with lime, and the calcium succinate decomposed by sulphuric acid; it is also formed by fermentation of calcium malate. Synthetically it can be obtained in many ways, *e.g.* from malonic acid (*q.v.*), and in a similar way from ethyl acetoacetate (*q.v.*); from ethylene by the following reactions:

$$\begin{array}{l}CH_2\\ \Vert\\ CH_2\end{array} \xrightarrow{Br} \begin{array}{l}CH_2Br\\ \mid\\ CH_2Br\end{array} \xrightarrow{KCN} \begin{array}{l}CH_2CN\\ \mid\\ CH_2CN\end{array} \xrightarrow{H_2O} \begin{array}{l}CH_2COOH\\ \mid\\ CH_2COOH\end{array}$$

With phosphorus pentachloride it gives either the anhydride or succinyl chloride:

$$\left.\begin{array}{l}CH_2.CCl_2\\ \mid\\ CH_2.CO\end{array}\right\rangle O$$

Its sodium salt on distillation yields *p*-diketohexamethylene:

$$\begin{array}{l}CH_2COONa\\ \mid\\ CH_2COONa\end{array} + \begin{array}{l}NaOOC.CH_2\\ \qquad\quad\mid\\ NaOOC.CH_2\end{array} = 2Na_2CO_3 + \begin{array}{l}CH_2-CO-CH_2\\ \mid\qquad\qquad\quad\mid\\ CH_2-CO-CH_2\end{array}$$

When heated with phosphorus trisulphide it yields thiophene (*q.v.*) *See also* Resorcin.

Succinimide (*Chem.*) *See* Pyrrole.

Suction (*Eng., etc.*) The drawing of fluid into a vacuum produced by the movement of a piston or plunger in a pump barrel.

Suction Pump. *See* Pumps.

Suffolks. *See* Bricks.

Sugar Cane. Cane sugar is prepared from the juice of the stem of a tall, strong perennial grass, *Saccharum officinarum* (order, *Gramineæ*), growing in tropical and subtropical regions. Molasses, treacle, and rum are derived from the sugar cane.

Sugar made from Rags, etc. (*Chem.*) *See* CELLULOSE.

Sugars (*Chem.*) Compounds: (1) of the formula $R - (CHOH)_n - CHO$, where R is hydrogen or occasionally CH_3 and $n = 1, 2, 3, \ldots$ etc.; (2) of the formula $R - (CHOH)_n - CO - CH_2OH$, where R and n have the same meaning as in (1); (3) derived from (1) and (2) by anhydride formation between a member from each or between two members from (1) or between two members of (1) and one member of (2). Members of Class (1) are called aldoses because they are all aldehydes; members of Class (2) are called ketoses because they are all ketones. Members of each class are distinguished by the number of carbon atoms they contain (not counting R), and it will be seen that the simplest member of Class (1) contains two carbon atoms—

$$\begin{array}{c} CH_2OH \\ | \\ CHO \end{array}$$

It is a biose; the simplest member of Class (2) contains three carbon atoms—

$$\begin{array}{c} CH_2OH \\ | \\ CO \\ | \\ CH_2OH \end{array}$$

It is a triose, and to distinguish it from the triose of Class (1)—

$$\begin{array}{c} CH_2OH \\ | \\ CHOH \\ | \\ CHO \end{array}$$

the former is a ketotriose and the latter is an aldotriose. A mixture of these two trioses is obtained by the cautious oxidation of glycerine (*q.v.*), and has been called glycerose, and glycerose has been used in the synthesis of sugars. *See* DEXTROSE. The six carbon atom sugars are called hexoses, also saccharoses; members of Class (3), derived from two saccharoses, are called disaccharoses, etc. (sometimes disaccharides). Most of the sugars are known by names given to them before any systematic way of naming them was in use, and these names are retained; also the above names serve only as class names, and would not serve to distinguish between stereoisomers, which are very numerous in the sugars. Examples of sugars are: Biose (glycollic aldehyde),

$$\begin{array}{c} CH_2OH \\ | \\ CHO \end{array}$$

trioses, glycerose; tetroses, erythrose (*see under* ERYTHRITOL); tetroses, arabinose (*q.v.*); methylpentose, rhamnose (*q.v.*); hexoses, dextrose (*q.v.*), lævulose (*q.v.*), galactose (*q.v.*); disaccharoses, cane sugar (*q.v.*), maltose (*q.v.*), lactose (*q.v.*); trisaccharoses, raffinose (*q.v.*) For the properties of a typical aldose, *see* DEXTROSE; of a typical ketose, *see* LÆVULOSE. *See also* OSAZONES *and* OXIMES.

Suint. The natural grease impregnating freshly cut sheep's wool. It is the raw material from which lanoline (*q.v.*) is prepared.

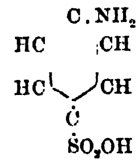
Suite. (1) A series of apartments connected together. (2) A number of pictures illustrating consecutive events.

—— (*Music*). A set of dance tunes in one key. The precursor of the SONATA (*q.v.*)

Suivez (*Music.*) A term warning an accompanist to be extra watchful.

Sullage (*Met.*) Dross, scoriæ, etc., which collect on the surface of fluid metal.

Sulphanilic Acid (*Chem.*)



Crystallises in rhombic plates containing one molecule of water; sparingly soluble in cold water, more soluble on boiling; the crystals effloresce; fused with caustic potash, it gives aniline; bromine water converts it into tribromaniline; on oxidation with manganese dioxide and sulphuric acid it gives quinones; it is easily diazotised. To prepare it aniline (100 parts) and sulphuric acid (105 parts) are heated at 180° to 220°, till all the aniline is changed. Sulphanilic acid is largely used in the preparation of dyes, *e.g.* methyl orange.

Sulphate of Baryta (*Min.*) A synonym for Barytes (*q.v.*)

Sulphate of Iron (*Min.*) *See* COPPERAS.

Sulphate of Lead (*Min.*) *See* ANGLESITE.

Sulphate of Lime (*Min.*) *See* GYPSUM.

Sulphate of Strontia (*Min.*) *See* CELESTINE.

Sulphates (*Chem.*) Salts derived from sulphuric acid. The more important sulphates are described under the respective metals, *q.v.*

Sulphating (*Elect. Eng.*) A defect due to the formation of lead sulphate on the plates of a secondary or storage cell.

Sulphides (*Chem.*) Compounds formed by the union of sulphur with another element or group of elements acting as a single element. The metallic sulphides may be regarded as salts of sulphuretted hydrogen. The more important sulphides are described under the respective metals, etc.

Sulphites (*Chem.*) Salts derived from sulphurous acid. The more important sulphites are described under the respective metals, etc.

Sulphite Wood Pulp (*Paper Manufac.*) Pulp prepared from wood by treatment with bisulphite of lime under pressure. *See* WOOD PULP.

Sulphocyanates (*Chem.*) (*also called* **Sulphocyanides**). Salts of the unstable sulphocyanic acid, HCNS. The most important sulphocyanates are those of potassium, ammonium, mercury, and silver. Ammonium sulphocyanate closely resembles the potassium salt (*see* POTASSIUM COMPOUNDS); it is obtained by warming a mixture of alcohol, ammonia, and carbon disulphide; like the cyanate, it undergoes rearrangement on heating—forms sulphourea. *See* GUANIDINE. The mercuric salt, $Hg(CNS)_2$, is formed by double decomposition; it is the substance used in making Pharaoh's serpents. The silver salt, AgCNS, is also made by double decomposition, and is

insoluble in nitric acids. Ferric sulphocyanate gives a blood red coloration in water, and its formation is used as a delicate test for ferric salts.

Sulphonal (*Chem.*) $(CH_3)_2C(SO_2C_2H_5)_2$ (Diethyl sulphone dimethylmethane). Thick, colourless prisms; melts at 126°; boils about 300°; sparingly soluble in cold water, much more soluble in hot water; sparingly soluble in alcohol; soluble in chloroform. It is a good hypnotic, and is used in medicine. It is a very stable substance; heated with potassium cyanide or charcoal it gives a smell of mercaptan; fused with caustic potash it gives a smell of mustard oil. It is prepared by treating sodium ethyl thiosulphate (from aqueous solution of sodium thiosulphate by heating with ethyl bromide) with acetone and hydrochloric acid, when acetone mercaptol is obtained. The thiosulphate and hydrochloric acid give mercaptan,

$$(CH_3)_2CO + 2HS.C_2H_5 = (CH_3)_2C(SC_2H_5)_2 + H_2O.$$

The acetone mercaptol on oxidation with potassium permanganate gives sulphonal. Also obtained by condensing aldehyde and mercaptan with hydrochloric acid, oxidising the product with potassium permanganate, and dissolving the ethylidene diethylsulphone with methyl iodide in benzene, and adding sodium:

$$CH_3CHO \xrightarrow[HSC_2H_5]{} CH_3CH\Big\langle{}^{SC_2H_5}_{SC_2H_5} \xrightarrow[O]{}$$

Ethylidene Mercaptol, B.P. 186°

$$CH_3CH\Big\langle{}^{SO_2C_2H_5}_{SO_2C_2H_5} \xrightarrow[CH_3I + Na]{} (CH_3)_2C(SO_2C_2H_5)_2$$

Ethylidene Diethylsulphone, M.P. 75°.

Sulphonation (*Chem.*) The operation of making sulphonic acids.

Sulphonic Acids (*Chem.*) Acids of the formula $R.SO_2.OH$. They are strong acids isomeric with the corresponding sulphites. The alkaline sulphites, however, have most probably the sulphonic constitution. Examples of inorganic sulphonic acids are chlorosulphonic acid, $SO_2\Big\langle{}^{Cl}_{OH}$, from sulphuric acid by the action of phosphorus pentachloride, and hydroxylamine disulphonic acid (salts only known), obtained by passing sulphur dioxide in a solution in molecular proportions of potassium nitrate and bicarbonate—

$$HO.NO + 2H.SO_2OH = HO.N(SO_2OH)_2 + H_2O$$

The sulphonic acids of the fatty series are not very important; they may be obtained by oxidising mercaptans (*q.v.*) with nitric acid. Taurine (*q.v.*) is a fatty sulphonic acid of physiological interest. The aromatic sulphonic acids are of great technical importance; unlike the fatty acids, they can be obtained by the direct action of sulphuric acid on aromatic compounds. All sulphonic acids yield chlorides when their alkali salts are treated with phosphorus chlorides, and the sulphonic chlorides easily yield sulphonamides when treated with ammonium carbonate—

$$R.SO_3K \xrightarrow[PCl_5]{} RSO_2Cl \xrightarrow[NH_4HCO_3]{} RSO_2NH_2$$

For examples of sulphonic acids, *see* BENZENE SULPHONIC ACID; the various NAPHTHALENE DERIVATIVES; SACCHARIN; SULPHANILIC ACID.

Sulphur (*Chem.*) S. Atomic weight, 32·06. A yellow solid element which belongs to the same chemical family as oxygen, Group VI. of the Periodic System. It is capable of existing in many different forms: α- or rhombic form: this occurs naturally, and is obtained in octahedral crystals, when any solution of sulphur in carbon disulphide is allowed to evaporate at the ordinary temperature; it melts at 114·5°. This form can exist in various crystalline modifications. β- or monoclinic sulphur is obtained in monoclinic prisms by melting sulphur, allowing it to cool till a crust forms, piercing the crust in several places, and pouring out the still liquid sulphur; it melts at 119·25°, is soluble in carbon disulphide, and exists in at least three crystalline modifications. The transition point for α- and β-sulphur is 95·5°; but if α-sulphur is heated somewhat above this temperature it will not pass into the β-form, owing to phase inertia. On touching it with a crystal of β-sulphur it will change at once; similarly β-sulphur can persist for a while, but ultimately passes into the α-form at the ordinary temperature. When benzene is saturated with sulphur at its boiling point, the solution will deposit the β-form above 75°, then a mixture of β- and α-forms till 22°, below which α-sulphur crystallises out. The change of β to α is accompanied by evolution of heat. When sulphur near its boiling point is poured into cold water, plastic sulphur is obtained, an elastic solid becoming brittle on standing, and insoluble in carbon disulphide. MILK OF SULPHUR, which is used in medicine, is amorphous and soluble in carbon disulphide; it is obtained by boiling flowers of sulphur (2 parts) with quicklime (1 part) which has been slaked with 3 parts of water, and 13 parts of water, and precipitating the solution with hydrochloric acid. When sulphur is heated above its melting point, it changes from a pale yellow liquid to a red liquid at 156°, increases in viscosity to a maximum at 180°, and then diminishes in viscosity to its boiling point at 444·5°. Its vapour density just above its boiling point indicates a complex molecule, probably S_8, but about 1,000° its vapour density corresponds to that of a diatomic molecule, S_2. Its molecular weight, determined by the lowering of the freezing point (in naphthalene) and by the raising of the boiling point (in carbon disulphide), corresponds to S_8. Sulphur combines directly with most of the other elements on heating, and with some at the ordinary temperature. In air it slowly combines with the oxygen at the ordinary temperature, forming the dioxide; in oxygen it unites at about 275° or in air at 360°, and burns with a blue flame; the principal product being the dioxide, only a trace of the trioxide is formed. It combines with mercury and silver at the ordinary temperature. Sulphur occurs uncombined in all volcanic regions. In combination it occurs as sulphides, such as iron pyrites, FeS_2, copper pyrites, $CuFeS_2$, galena, PbS, zinc blende, ZnS, cinnabar, HgS, stibnite, Sb_2S_3, orpiment, As_2S_3, realgar, As_2S_2; as sulphates, such as gypsum, $CaSO_4 2H_2O$ (*see also* ALABASTER *and* SELENITE), heavy spar, $BaSO_4$, celestine, $SrSO_4$, kieserite, $MgSO_4H_2O$; it also occurs in combination in hair, proteids, mustard oils, bile acids, and as sulphuretted hydrogen in many mineral springs. Most sulphur is obtained in Sicily; the crude sulphur is built up in stacks on a sloping floor, the stack being covered with spent stuff from a previous operation; air openings are provided in the stack and cover, and the sulphur is ignited, when it melts and flows out at the lowest part of the floor into troughs. It is purified by distillation in an iron retort, and condensation in a large brick chamber; the first portions are solid and form the flowers of sulphur of com-

merce; but when the chamber gets hot the sulphur melts, and this part is cast, forming ordinary stick sulphur. A certain amount of sulphur is obtained from alkali waste by Chance's process (*q.v.*)

Sulphur (*Min.*) Native sulphur; orthorhombic, also massive and in incrustation; yellow to reddish. It is one of the group of minerals often associated with Gypsum. Rarely found in metalliferous veins, as at Dufton mines in Westmorland. Considerable deposits occur in volcanic regions, as in Sicily, near Naples, in Iceland, Java, etc. Also from Spain, Chile, California, Hawaii, etc.

Sulphur Compounds (*Chem.*) HYDROGEN SULPHIDE, H_2S (Sulphuretted hydrogen). Is a colourless gas; melts at $-86°$; boils at $-62°$; soluble in water (1 vol. of water dissolves 3·23 vols. of the gas at 15°). It has a fœtid smell and is very poisonous (0·05 per cent. in air produces marked symptoms of poisoning in a few minutes). On heating, the gas begins to decompose into its elements at 400°. It burns easily in air or oxygen—to sulphur dioxide and water when the supply of oxygen is sufficient; to sulphur and water otherwise. The halogens decompose it, chlorine, for example, giving sulphur and hydrochloric acid, or if the halogen is in excess, sulphur chloride and hydrochloric acid. Many metals decompose it: thus silver is blackened by it, being changed to sulphide, and tin, when heated in the gas, also decomposes it. Hydrogen sulphide is a reducing agent, as the following examples show:

$$2FeCl_3 + H_2S = 2FeCl_2 + 2HCl + S$$
$$2KMnO_4 + 4H_2SO_4 + 5H_2S = 2KHSO_4 + 2MnSO_4 + 8H_2O + 5S$$
$$2H_2S + SO_2 = 2H_2O + 3S$$

A solution of the gas in water behaves as a feeble acid; when the gas is passed into solutions of alkalis it forms salts: $2KOH + H_2S = K_2S + 2H_2O$ and $KOH + H_2S = KSH + H_2O$. On passing the gas into a solution of a salt of a metal which forms a sulphide insoluble in water, that sulphide is precipitated, completely if the sulphide is insoluble in the dilute acid liberated, incompletely if the sulphide is soluble in the dilute acid liberated, *e.g.*

$$HgCl_2 + H_2S = \underset{\substack{\text{Insoluble.}\\ \text{Precipitation complete.}}}{HgS} + 2HCl$$

$$ZnSO_4 + H_2S = \underset{\substack{\text{Soluble.}\\ \text{Precipitation incomplete.}}}{ZnS} + H_2SO_4$$

Hence the use of hydrogen sulphide as a reagent in qualitative analysis (*q.v.*) Sulphuretted hydrogen occurs as a product of the putrefaction of proteid; it also occurs in many mineral waters, such as those of Strathpeffer and Harrogate. It is obtained by passing hydrogen into boiling sulphur or for ordinary laboratory purposes by the action of dilute hydrochloric or sulphuric acids on ferrous sulphide. When required pure, black antimony sulphide is heated with concentrated hydrochloric acid. The gas is easily recognised by its turning strips of filter paper which have been dipped in lead acetate solution black, or by its smell. *Halogen Compounds:* The HEXAFLUORIDE, SF_6, is a colourless, odourless, and very stable gas; it is obtained by the direct action of fluorine on sulphur, when the sulphur burns and forms a mixture of fluorides. The mixture is liquefied at $-80°$, fractionally distilled, treated with concentrated caustic potash, and dried over solid potash. SULPHUR MONOCHLORIDE, S_2Cl_2, is a reddish yellow liquid; boils at 138°; has unpleasant smell; readily dissolves sulphur, and is on this account used in vulcanising indiarubber; it is decomposed by water, but not in a simple way. Among the products are sulphur, sulphur dioxide, and hydrochloric acid; metals yield chlorides and sulphur. It is prepared by passing dry chlorine over gently heated sulphur, leaving some undissolved sulphur, and rectifying the product till it boils constantly at 138°. The remaining halogen compounds are unimportant. *Oxides:* SULPHUR DIOXIDE, SO_2 (Sulphurous anhydride), is a colourless gas; melts at $-76°$; boils at $-8°$; has a keen, choking smell; very soluble in water; at 0° 1 vol. water dissolves 79·79 vols. of the gas, and at 20°, 39·37 vols. It is a very heavy gas, being just over two and a quarter times as heavy as air. Sulphur dioxide is decomposed by strong sunlight to sulphur and sulphur trioxide, and electric sparks produce the same effect, but the decomposition is not complete. It unites directly with chlorine in sunlight to form sulphuryl chloride, $SO_2 + Cl_2 = SO_2Cl_2$. It unites with oxygen when the two gases, dried over sulphuric acid, are passing over heated platinum black, $SO_2 + O = SO_3$. A number of metals burn in it when heated, forming sulphides and oxides, and in the case of potassium, sulphite and thiosulphate; lead dioxide unites energetically with it to form lead sulphate. The solution of sulphur dioxide in water behaves as a weak dibasic acid—SULPHUROUS ACID, $SO_2 + H_2O = H_2SO_3$; its salts are called SULPHITES. Sulphurous acid unites with oxygen to form sulphuric acid, and is therefore a reducing agent, a disinfectant, and a bleaching agent. As examples of its reducing action may be given:

$$Fe_2(SO_4)_3 + H_2SO_3 + H_2O = 2FeSO_4 + 2H_2SO_4$$
$$\underset{\text{Orange.}}{2CrO_3} + 3H_2SO_3 = \underset{\text{Green.}}{Cr_2(SO_4)_3} + 3H_2O$$

As a disinfectant it is used in rooms which have been occupied by persons suffering from infectious diseases. As a preservative it is used in solution for painting over meat in warm weather. In bleaching it is used for material which would be injured by chlorine, such as blankets and straw. The gas may be prepared in a variety of ways, *e.g.* by burning sulphur in air or oxygen, by the action of most acids on sulphites, by heating copper, mercury, silver, or carbon with concentrated sulphuric acid when the latter is reduced to sulphurous acid. The gas is easily detected by its smell and its property of turning a strip of filter paper moistened with a solution of a chromate green. SULPHUR TRIOXIDE, SO_3 (Sulphuric anhydride), is a white solid crystallising in silky needles or in prisms; melts at 15°; combines with great energy with water to form sulphuric acid, and with basic oxides to form salts: thus barium oxide becomes red hot and forms the sulphate. It is prepared by direct union of the dioxide and oxygen in presence of heated, finely divided platinum. Both gases must be dry, and so, too, the apparatus; it may also be prepared by distilling fuming sulphuric acid. By the former of these methods it is prepared on a very large scale for the manufacture of concentrated sulphuric acid and fuming sulphuric acid. SULPHURIC ACID, H_2SO_4 (oil of vitriol), is a colourless oily liquid which fumes slightly in air; melts at 10·5°; sp. gr. at 15°, 1·838; boils, with decomposition into anhydride and water, and its boiling point attains a maximum at 338°. The ordinary pure concentrated acid of the laboratory contains about 95·6 per cent. H_2SO_4, and has a specific gravity of 1·84 at 15°. Acid of 97·7 per cent. has a specific gravity of 1·8415, and acid of 99·2 per cent. has again a specific gravity of 1·84. The acid of strength between the last two

appears to have some remarkable properties; thus it absorbs sulphur trioxide far better than at any other concentration; the maximum boiling point is possessed by an acid of 98·5 per cent.; further, acid over 97·7 per cent. has a peculiar action on cast iron, for when heated in cast iron vessels they do not appear to be attacked, but after a while they will suddenly break. Such acid can be heated in wrought iron vessels without these being attacked. Sulphuric acid unites with water to form several definite hydrates, *e.g.* $H_2SO_4H_2O$, which is a crystalline solid and melts at 8°, and $H_2SO_4 4H_2O$, which melts at −25°. On mixing the acid with water, much heat is given out; the mixture in gram molecular proportions evolves 6,336 calories, while every extra gram molecule of water added gives a less and less amount: thus, when 5 gram molecules of water have been added, the total heat evolved is 13,020 calories. On account of its affinity for water, sulphuric acid is often used as a drying agent: thus gases not acted on by it are bubbled through it to dry them, and substances are often dried by exposing them in a basin over strong sulphuric acid in a closed vessel (desiccator), which may or may not be exhausted of air. Also the acid will often take away the elements of water from a compound when allowed to stand with it, or on heating with it; *e.g.* blue copper sulphate becomes white, formic acid on heating gives carbon monoxide, oxalic acid gives both oxides of carbon, cane sugar gives charcoal and water. The more easily oxidisable metals are oxidised to sulphates when heated with the strong acid, while the part of the acid which has effected the oxidation is reduced to sulphurous acid. Many ring compounds are converted by heating with the strong acid into sulphonic acids (*q.v.*) When the strong acid is heated with salts of acids more volatile than sulphuric acid, a sulphate is formed, and the more volatile acid will escape if the reaction mixture is kept at a suitable temperature: the preparation of hydrochloric acid, nitric acid, and glacial acetic acid are illustrations of this statement. The diluted acid has the properties of a strong dibasic acid, dissolving many metals, with liberation of hydrogen and formation of a sulphate, and converting many basic oxides, hydroxides, carbonates, and sulphides to sulphates. The less concentrated acid is prepared by allowing a mixture of sulphur dioxide, air, higher oxides of nitrogen, and steam to react in leaden chambers at about 60°, when a complex series of reactions occurs, such as—

$$SO_2 + H_2O + NO_2 = H_2SO_4 + NO$$
$$NO + O = NO_2$$

$$2SO_2 + H_2O + NO_2 + NO + O_2 = 2SO_2\left\langle\begin{matrix}OH\\NO_2\end{matrix}\right.$$

$$2SO_2\left\langle\begin{matrix}OH\\NO_2\end{matrix}\right. + H_2O = 2SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. + NO_2 + NO$$

from which it is seen that the oxides of nitrogen act only as carriers of oxygen. The most concentrated acid and also fuming sulphuric acid are prepared by passing washed dust free and dried sulphur dioxide and excess of air over platinised asbestos, which is heated to about 425° to start the reaction, then cooled by the entering gases subsequently, as the reaction once started evolves heat. Ordinary concentrated sulphuric acid (95·6 per cent., H_2SO_4) can be converted into 100 per cent. acid by freezing or by adding the calculated quantity of sulphur trioxide. *See* SULPHURIC ACID MANUFACTURE. Sulphuric acid is used on an enormous scale in the manufacture of sodium carbonate; of other acids, such as nitric and hydrochloric and acetic; in oil refining, in indigo making, in the manufacture of many dyes. ACID CHLORIDES OF SULPHURIC ACID: (1) Chlorosulphonic acid, $SO_2\left\langle\begin{matrix}Cl\\OH\end{matrix}\right.$, is a colourless fuming liquid; boils at 152°. It is obtained by the direct union of sulphur trioxide and hydrogen chloride—

$$SO_3 + HCl = SO_2\left\langle\begin{matrix}Cl\\OH\end{matrix}\right.$$

and by the action of phosphorus pentachloride on sulphuric acid—

$$SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. + PCl_5 = SO_2\left\langle\begin{matrix}Cl\\OH\end{matrix}\right. + POCl_3 + HCl$$

(2) Sulphuryl chloride, $SO_2\left\langle\begin{matrix}Cl\\Cl\end{matrix}\right.$, is a colourless fuming liquid; boils at 69°. It is occasionally used as a chlorinating agent in organic chemistry. It is made by the direct action of chlorine on sulphur dioxide in sunlight, or by boiling chlorosulphonic acid with mercuric sulphate (1 per cent.: it acts as a catalytic agent). Both these chlorides of sulphuric acid are of interest as throwing light on the constitution of sulphuric acid, for besides the methods of formation which show their relation to sulphuric acid very clearly, they are both decomposed by water into hydrochloric and sulphuric acids—

$$SO_2\left\langle\begin{matrix}OH\\Cl\end{matrix}\right. + HOH = SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. + HCl$$

$$SO_2\left\langle\begin{matrix}Cl\\Cl\end{matrix}\right. + 2HOH = SO_2\left\langle\begin{matrix}OH\\OH\end{matrix}\right. + 2HCl$$

FUMING SULPHURIC ACID, $H_2S_2O_7$ (Nordhausen sulphuric acid; Disulphuric acid; Pyrosulphuric acid), is a colourless, oily, fuming liquid. It gives off sulphur trioxide on warming. Unites with great energy with water. It is used in the preparation of aromatic sulphonic acids. It forms a definite series of salts, of which the sodium salt is typical. This salt is obtained by carefully heating acid sodium sulphate—

$$\begin{matrix}SO_2\left\langle\begin{matrix}ONa\\OH\end{matrix}\right.\\SO_2\left\langle\begin{matrix}OH\\ONa\end{matrix}\right.\end{matrix} = \begin{matrix}SO_2\left\langle\begin{matrix}ONa\\ \end{matrix}\right.\\SO_2\left\langle\begin{matrix} \\ONa\end{matrix}\right.\end{matrix} + H_2O$$

The acid is prepared by passing sulphur trioxide into concentrated sulphuric acid, also by distilling partially roasted ferrous sulphate. As a manufacturing process the latter method has been replaced by the former. Ordinary fuming sulphuric acid is usually a mixture of disulphuric acid and ordinary sulphuric acid or sulphur trioxide, according to the strength of the fuming acid. PERSULPHURIC ACID,

$$H_2S_2O_8 = SO_2\left\langle\begin{matrix}OH\,HO\\O-O\end{matrix}\right\rangle SO_2$$

The pure substance is unknown. An aqueous solution is obtained by decomposing barium persulphate with dilute sulphuric acid. The anhydride is obtained by passing a silent electric discharge through a mixture of sulphur dioxide and oxygen, as an oil which crystallises at 0°, and has the formula S_2O_7; but when water acts upon this it decomposes in part

to sulphuric acid and oxygen. When strong sulphuric acid acts on a persulphate, persulphuric acid is liberated, but a part of it reacts with the sulphuric acid to form another acid—anhydromonopersulphuric acid. When strong sulphuric acid is electrolysed or treated with hydrogen peroxide, persulphuric acid is formed, but the excess of sulphuric acid converts some of it to anhydromonopersulphuric acid. It forms a whole series of salts, of which the potassium salt is the least soluble. *See* POTASSIUM COMPOUNDS.

ANHYDROMONOPERSULPHURIC ACID (Caro's acid): Monopersulphuric acid has the formula $SO_2\left\langle\begin{matrix}O-OH,\\OH\end{matrix}\right.$ but it is unknown. Its anhydride, therefore, will have the formula

$$SO_2\left\langle\begin{matrix}O-OHHO-O\\O\end{matrix}\right\rangle SO_2$$

which is Caro's acid. This acid is not known pure, but forms a pretty stable sulphuric acid or phosphoric acid solution, which also contains persulphuric acid. Such a solution may be obtained by grinding one part of potassium persulphate with two parts of concentrated sulphuric acid, allowing to stand an hour, pouring on to ice, and precipitating sulphuric acid by barium phosphate. That it has the anhydride formula is shown by the fact that its calcium salt on hydrolysis decomposes thus:

$$CaS_2O_9 + H_2O = CaSO_4 + H_2SO_4 + 2O$$

Caro's acid is much used as an oxidising agent in organic chemistry. *See* NITROSO COMPOUNDS.

THIOSULPHURIC ACID, $H_2S_2O_3 = SO_2\left\langle\begin{matrix}OH\\SH\end{matrix}\right.$. The free acid is unknown, for when an acid is added to a thiosulphate to liberate thiosulphuric acid, the liberated acid immediately begins to decompose—

$$H_2S_2O_3 = H_2O + SO_2 + S$$

See THIOSULPHATES *and* SODIUM COMPOUNDS. Other sulphur acids are known, *e.g.* Dithionic acid, $H_2S_2O_6$; Trithionic acid, $H_2S_3O_6$, etc., up to Hexathionic acid, $H_2S_6O_6$. For other inorganic sulphur compounds *see* CARBON DISULPHIDE, HYPOSULPHUROUS ACID, *and* HYPOSULPHITES. Many organic sulphur compounds are known (*e.g. see* MERCAPTANS, MUSTARD OILS, SULPHONIC ACIDS). When four different monovalent atoms or radicals are united to a sulphur atom, stereoisomerism is possible (asymmetric sulphur atom). Thus, when *a*-bromacetophenone and methylethyl sulphide are allowed to act on each other, they readily react to form methylethylphenacylsulphine bromide—

$$\begin{matrix}CH_3\\C_2H_5\end{matrix}\Big\rangle S + BrCH_2CO\,.\,C_6H_5 = \begin{matrix}CH_3\\—\end{matrix}\Big\rangle S\Big\langle\begin{matrix}CH_2COC_6H_5\\Br\end{matrix}$$

This compound, when boiled in alcoholic solution with silver *d*-bromocamphorsulphonate, yields a salt which by fractional crystallisation can be separated into the *d*-bromocamphorsulphonate of the lævo-base, which is the less soluble, and the *d*-bromocamphorsulphonate of the dextro-base, which is contained in the mother liquors, and is purified by crystallisation from acetone.

Sulphuric Acid Manufacture. CHAMBER PROCESS: The "chamber" into which the nitroxygen gases, sulphur dioxide, and steam (or atomised water) are led in order to form the "rain" of acid is a large rectangular arrangement composed of a "saucer" and "curtain" (*q.v.*) usually supported on a floor carried by brick pillars about 12 or 15 ft. above the ground. The curtain is suspended by straps of sheet lead from a wooden framework or scaffolding. The yield of acid is gauged by the "acid drip" (*q.v.*) The sulphur dioxide passes up the Glover Tower (*q.v.*) before entering the chamber, while the exit gases are scrubbed with sulphuric acid in a Gay Lussac Tower (*q.v.*) in order to retain any nitroxygen gases that may escape. These are returned to the chamber by means of the Glover Tower. The resultant chamber acid is syphoned out of the saucer and concentrated to a specific gravity of 1·7. It is also further rectified in glass or platinum lined retorts. The commercial products are known as B. O. V. (Brown Oil of Vitriol) and R. O. V. (Rectified Oil of Vitriol). The size and disposition of the chambers are of importance. It is now customary to allow 12 or 13 ft. of chamber space per lb. of sulphur burnt; also the chambers should be at least four times as long as they are high. The introduction of the gases at the bottom of the chamber is now accepted as preferable. The object of such large chambers is to dissipate the heat evolved during the chemical reaction. The introduction of PLATE TOWERS between the chambers, in a series, is now often adopted, the passage of the gases being assisted and controlled by fans. These plate towers are rectangular or round, and are packed with porcelain saucers or reticulated plates about 3 ft. in diameter, down which water or weak acid passes, meeting the gases as they ascend. A system of tangential chambers is being introduced, but at present is only in the experimental stage, though on the large scale. The nitroxygen gases required (*vide* Chamber Reactions, *supra*) are always obtained by heating cubic nitre (nitrate of sodium), commonly known as Chili saltpetre, with sulphuric acid in nitre pots. The source of the sulphur is of considerable importance, and the finished product is generally classified for trade purposes as pyrites acid, spent oxide acid, and brimstone acid, according to the source of sulphur. There is always the risk of arsenical contamination when iron pyrites (FeS_2) is used (*see* PYRITES BURNER), which is objectionable in the case of acid destined for use in the brewing or mineral water industries. Brimstone acid is the purest for such purposes, being made with sulphur dioxide obtained by burning Sicilian sulphur. Spent oxide acid is also virtually a pure sulphur acid, since spent oxide is hydrated oxide of iron which has been saturated with sulphur compounds and free sulphur in the purification of coal gas (*q.v.*) It is often preferred on this account for the manufacture of sulphate of ammonia, which is largely used as a fertiliser, in which arsenical compounds would be objectionable. Care must be exercised when working with unwashed spent oxide, or trouble will be experienced with the acidity of the chamber exit, which is restricted by law to 4 grains per cubic foot, calculated as sulphuric anhydride. The average acidity from all chambers in the United Kingdom during the past few years has been about 1·2 grains per cubic foot. Some spent oxides rich in ammonia and other nitrate-consuming compounds cannot be used without previous washing. Though the chemistry of the formation of sulphuric acid is at first sight comparatively simple, the actual reactions taking place in the chamber have long been the subject of much controversy. The loss of nitre has always been a mystery that it has been sought to solve by many theories. Undoubtedly the amount of steam admitted into the chamber has much to do with successful working, though this has to be regulated so as to keep the yield of chamber acid at or below 1·6 sp. gr. The careful working of the Gay Lussac Tower is another important factor, particularly in

relation to the loss of nitre. Thanks, however, to physio-chemical researches in connection with the fractional distillation of liquefied gases, it has been possible to dispose of most theoretical arguments concerning the loss of nitre, for in this way it has been proved that the loss is due to mechanical conditions arising from working on a large scale. There is practically no chemical loss, and hydroxylamine products are not formed in the normal working of a chamber (J.S.C.I. vol. xxiii. p. 643). The establishment of this fact is of great assistance, as it points directly to the sections of the plant which must be watched for the leakage of nitre. By the aid of the Plate towers the loss has been reduced to 1·3 parts per 100 of sulphur. CATALYTIC OR CONTACT PROCESS: This method is confined to the production of sulphuric anhydride (SO_3) and very concentrated sulphuric acid, chiefly in Germany and the United States of America. In 1888 only 18,500 tons were being produced by one contact process, which in 1900 had increased its output to 116,000 tons. In 1903 there were twenty-three plants abroad working the Schroeder contact process, apart from other patents. In this country, however, there are only three works—two in England and one in Scotland. Much difficulty is experienced in keeping the acid exit below the legal limit, and H.M. Chief Inspector of Alkali. etc., Works, expresses the opinion that, owing to the limited uses for such concentrated acid, the extension of this process is not anticipated. It is cheaper than concentration for the production of SO_3, but for acid below 60° B. it cannot profitably compete with the chamber process. The process has been briefly described under SULPHUR TRIOXIDE (*vide supra*), but the following additional points are of interest. The contact material requires to be kept at about 400°. There is no reaction at 200°, but at 900° dissociation takes place, the trioxide formed from the mixture of SO_2 and air (1 : 3) reverting to the dioxide. As in the chamber process, it is most important to remove the heat of the reaction, which in this case amounts to 22,600 calories. The composition of the mixture of SO_2 and air, and also the rate of flow, are factors affecting the production. The presence of arsenic in pyritic SO_2 is very soon fatal to the contact material, and great care has to be exercised in keeping this and other impurities out of the reacting gases. A vast number of catalytic agents have been suggested, but platinised asbestos or other allied material has so far been found best. The process is thus shown to be essentially a refinement of the laboratory method operated by Sir Humphry Davy in 1817.—C. H. N.

Sulphuric Ether (*Chem.*) A common name for ETHER (*q.v.*)

Sulphur in Iron (*Met.*) A small amount of sulphur renders iron RED SHORT or brittle when at a red heat; it also destroys its welding properties. The addition of manganese lessens the deleterious effect of the sulphur.

Sulphuryl Chloride (*Chem.*) *See* SULPHUR COMPOUNDS.

Sumach (*Botany*). The finely ground leaves of Sicilian Sumach, *Rhus Coriaria* (order, *Anacardiaceæ*), and the myrtle-leaved Sumach, *Coriaria Myrtifoliæ*, both cultivated in Southern Europe, constitute the tanning material known as sumach. *See also* DYES AND DYEING.

Summer Solstice (*Astron.*) *See* SOLSTICES.

Sump (*Mining*). Any excavation below the floor of a mine, especially a pit in which water collects.

Sun (*Astron.*) (1) The nearest of all stars and the centre of our system. A hot self-luminous body. Mean distance, 93,000,000 miles; diameter, 866,400 miles; period of rotation about 25d. 7h. The surface of the sun, the PHOTOSPHERE (*q.v.*) has a grey background covered with granular forms termed NODULES or RICE-GRAINS. Above this is the CHROMOSPHERE (*q.v.*), in which occurs the REVERSING LAYER whence the Fraunhofer's lines (*q.v.*) are supposed to originate. The FACULÆ (*q.v.*) are found in all parts. Beyond all these is the CORONA (*q.v.*), to be observed only during eclipses. The material of the sun, as revealed by the spectrum, has many elements that are known on the earth, while others have no counterparts. (2) Any star that is the centre of a system.

Sun and Planet Motion (*Eng.*) A device employed by Watt in place of a crank; this use is now obsolete; but it is now used in certain forms of Speed Gears (*q.v.*)

Sun Dial (*Astron.*) A rod termed a Gnomon or Style casts a shadow on a suitably divided plate. The position of the edge of the shadow indicates the Apparent Solar Time. *See also* MEAN SOLAR DAY.

Sunk Winding (*Elect. Eng.*) Conductors laid or wound in slots or grooves in the surface of an armature.

Sunk Work (*Build., etc.*) A recess or sinking below the general surface of an object.

Sunn Hemp (*Botany*). An Indian shrub, *Crotalaria juncea* (order, *Leguminosæ*), producing a valuable fibre for cordage, etc. It is prepared in a similar manner to Hemp and Flax.

Sunshine Recorder (*Metereol.*) An instrument for producing a continuous record (usually on photographic paper) of the time during which the sun shines each day. In some cases the intensity of the radiation received by the instrument is also recorded.

Sun Spot (*Astron.*) One of the apparent dark spots on the disc which appear from time to time, and which move across the disc owing to the solar rotation. Caused by relatively cool matter falling towards the centre from the higher reaches of the solar atmosphere.

Sun Spot Periods (*Astron.*) The number of spots varies from year to year. The interval between the time when there are fewest spots to the next similar condition is about eleven years. There is possibly a longer period of about thirty-five years in addition.

Sunstone (*Min.*) This term is used for any of the Aventurine varieties of the Felspars (*see* PRECIOUS STONES). The characteristic appearance is due to spangles of mica included in the Felspar giving a golden reflection.

Supercalenders (*Paper Manufac.*) A stack of specially arranged polished rolls, used for imparting a very high surface to paper.

Supercooling *or* **Superfusion** (*Phys.*) A liquid which is free from solid particles can usually be cooled some distance below its freezing point if kept still. Movement, or the introduction of a piece of the solid, causes the liquid to solidify with evolution of latent heat and consequent rise of temperature.

Super-elevation (*Eng.*) The raising of the outer rail where a curve occurs in a railway. The object

is to counteract the centrifugal force, which tends to throw the vehicles off the rails when travelling at speed round the curve.

Superheated Steam (*Eng.*) *See* STEAM.

Superior Figures, Superior Letters (*Typog.*) Small figures or letters on the shoulder of type, used as references to footnotes, abbreviations, etc., *e.g.* ¹²³, ᵃᵇᶜ, N°· for number, ° for degree.

Superior Planets (*Astron.*) Those whose orbits lie outside that of the Earth, *i.e.* those which are more distant from the Sun. They are Mars, the Asteroids, Jupiter, Saturn, Uranus, and Neptune (*q.v.*)

Supernumerary Bows (*Meteorol.*) *See* RAINBOWS.

Super-octave (*Music*). A coupler in an organ which causes the note an octave above the note played to fall. *Cf.* SUB-OCTAVE.

Superphosphate (*Chem. Tech.*) A commercial term for monobasic phosphate of lime (*i.e.* soluble phosphate). Largely used as a source of phosphorus in the manufacture of compound fertilisers. Obtained by treating ordinary mineral phosphates (tribasic phosphate of lime), such as Somme, Florida, Algerian, or Carolina phosphate rock or pebbles, coprolites, etc., with sulphuric acid. Unless the tribasic phosphate is thoroughly converted by acid, there is a tendency to "revert" to dicalcic phosphate, which is insoluble.

Superphosphate of Lime (*Chem.*) *See* CALCIUM COMPOUNDS.

Super Royal (*Paper*). Printing paper of size $27\frac{1}{2} \times 20\frac{1}{2}$ in.; writing paper, 27×19 in.

Supersaturated Solutions (*Chem.*) *See* SOLUTIONS.

Supersaturation (*Phys.*) A saturated solution in which no solid particles of the dissolved substance are present can be cooled without deposition. The solution then contains more of the dissolved substance than corresponds to a saturated condition, and is said to be Supersaturated.

Supertonic (*Music*). Above the tonic. The technical name of the second note of a scale.

Supplement of an Angle. The difference between the angle and 180° or two right angles.

Supply Mains (*Elect.*) The mains or principal conductors by which electricity is distributed.

Supply Steam (*Eng.*) The steam at entrance to a cylinder, as distinguished from the EXHAUST STEAM.

Supporters (*Her.*) The figures which appear on each side of a shield, holding up or protecting the same. Their origin is uncertain. Supporters are borne by peers of the realm, by their sons who enjoy honorary titles, and by knights of various orders. They are also borne by persons of other rank, who have derived them from ancestors entitled to bear them. Spiritual peers do not bear supporters.

Surbase (*Architect.*) The cornice or upper moulding of a pedestal (*q.v.*)

Surcoat (*Cost.*) A loose outer garment; specifically, a loose, sleeveless coat or robe worn over armour in the Middle Ages, and girt in at the waist by the sword belt. The later examples were generally emblazoned with the arms of the wearer.

Surface Carburetter (*Motor Cars, etc.*) A form of vaporiser for petrol engines, in which a large surface of liquid is exposed to contact with air, evaporation occurring at the ordinary temperature of the atmosphere. In the commonest forms a large tank is nearly half filled with the liquid petrol or other motor spirit, and the air in the space above the liquid becomes charged with vapour. From this space the gaseous mixture is drawn into the cylinder through a supply pipe. The supply of air is admitted through a vertical pipe, the upper end of which opens into the atmosphere, while the lower end dips under the surface of the liquid in the tank. As the gaseous mixture is withdrawn, fresh air is drawn into the chamber through this pipe, and it can only reach the space above the liquid by passing through the latter in a series of bubbles, thus promoting evaporation. Valves are fitted for controlling the amount of the gaseous mixture drawn into the cylinder at each stroke, and also for regulating the amount of air in the mixture. The surface carburetter is now little used, on account of its large size and other objections, and the various forms of Spray Carburetter (*q.v.*) have largely superseded it.

Surface Condenser (*Eng.*) The device employed for condensing exhaust steam, without mixing it with cold water. The steam is brought into contact with a cold surface, in the form of a large number of brass tubes. These are cooled by a regular flow of cold water, the CIRCULATING WATER, which may flow through the tubes while the steam circulates round them, or *vice versâ*. By this means impure water or salt water may be used for condensing the steam, while the latter is kept pure and may be returned to the boiler after condensation. Surface condensation is now universally used in marine engines.

Surface Density (*Elect.*) The quantity of electricity per unit of area of a charged body.

Surface, Equipotential (*Phys.*) A surface such that the potential (*q.v.*) at any point has a constant value. The surface of a charged conductor is an example of an equipotential surface; the equipotential surfaces due to a charged sphere, at a distance from other bodies, are concentric spheres described in the medium surrounding the sphere.

—— **Measurement of.** *See* WEIGHTS AND MEASURES.

Surface Plate (*Eng.*) A plate of metal (or glass) whose surface has been made as nearly as possible a true plane. It is used for testing the accuracy of a plane surface such as that required to be produced on a slide valve, etc.

Surface Water (*Build.*) Rain water which collects on the surface of the ground and is generally carried off by drains.

Surfacing (*Eng.*) (1) Turning up a plane surface in the lathe; this is only possible when the surface is at right angles to the axis of the lathe. The tool moves across the lathe bed, at right angles to the axis; the slide rest is actuated either by hand or by gearing connected with a back shaft running along the back of the lathe bed; this shaft is itself rotated at a convenient speed by belts, etc., driven by the mandrel of the athe. (2) The term "surfacing" is also occasionally applied to the production of plane surfaces by comparison with a Surface Plate (*q.v.*),

irregularities being gradually removed by a SCRAPER (*q.v.*) This process, however, is more usually termed SCRAPING.

Surfacing Lathe (*Eng.*) Any lathe provided with mechanism for SURFACING (*q.v.*)

Surmounted Arch (*Build.*) A stilted semicircular arch, *i.e.* a semicircular arch rising more than its span or radius.

Surveying. Surveying, in the widest sense, embraces the operations by which are determined the form, dimensions, and levels of portions of the earth's surface, and of various works and structures permanently located thereon. These operations fall for the most part into three classes: (1) Measurement of Distances. (2) Measurement of Angles. (3) Levelling. (1) *Measurement of Distances.* This is effected in the great majority of practical cases by a CHAIN, whose length is usually 66 ft. (or in certain cases 100 ft.) The links, 100 in number, are made of straight pieces of steel wire, about 6 in. in length, with a loop at each end; consecutive links are joined by small loops, which, with the straight link, give a total length of 7·92 in. per link; every tenth link is numbered by means of a small brass tally. Points are marked by rods or ARROWS stuck into the ground where the end of the chain rests at each measurement; the ends of a line, or other important points or STATIONS, are marked by poles termed RANGING POLES, which are painted in prominent colours and may have a flag attached. Small distances may be measured with a TAPE, preferably of steel, or with MEASURING RODS. (2) *Measurement of Angles.* (*a*) The chain may be used in cases where the angle to be measured forms one of the angles of a triangle whose sides can be measured on the ground; the length of the three sides being known, the triangle is completely determined. (*b*) The majority of angular measurements are made by the THEODOLITE. This is in principle a telescope which can be turned about on either a vertical or a horizontal axis, the angles of rotation being measured by graduated circles provided with VERNIERS (*q.v.*) For ordinary measurements of horizontal angles, the instrument is set up at the apex of the angle to be measured, and the telescope is directed at a suitable object which is situated in one of the lines containing the angle; a ranging pole is often set up for this purpose. The vernier reading of the horizontal scale is then read, the telescope directed at a pole or other object in the second line containing the angle, and the vernier read again. The difference of the two readings is the angle required. When used for measuring vertical angles (*e.g.* in measuring the height of a lofty object), the telescope is rotated about the horizontal axis and the readings taken from the vertical circle. (*c*) For rough surveys or for filling in small details, the PRISMATIC COMPASS is often used. This is a magnetic compass having a "floating card," *i.e.* a circular card divided into degrees, and attached to the needle so as to turn with it; the instrument is provided with sights which are aligned with any given object; by means of a reflecting prism the sights and the graduations of the scale may be read simultaneously. Thus the angle between any given line and the direction in which the compass points may be read off. (*d*) The MINER'S DIAL, or CIRCUMFERENTER, is a compass of larger size than the foregoing, provided with sights which can be turned relatively to the box; the object is viewed through these sights, and the angle made by the line of sight with the direction of the needle read off. (*e*) The SEXTANT (*q.v.*) is sometimes used in angular measurement, a small portable form termed the BOX SEXTANT being very convenient for explorers. (3) *Levelling.* The LEVEL consists essentially of a telescope mounted on a vertical axis (without a graduated circle). A spirit level is contained in a "level tube" which is attached to the telescope, and provided with means of adjustment so that the axis of the telescope can be made accurately parallel with that of the level itself: thus when the bubble of the level is in its central position, the axis of the telescope is truly horizontal. In using the instrument to determine the difference of level of two adjacent points, a LEVELLING STAFF is set up at each station; this is a graduated rod of convenient height, the divisions being clearly marked so as to be distinctly visible through the telescope. If the instrument be placed between the stations, and turned so as to view the graduations of each staff in turn, the difference of the readings on the two staves gives the difference in level of the two points on which the feet of the staves are placed, provided that the instrument has first been correctly adjusted. For observing great differences in level, such as the height of a mountain, some form of barometer is often used, or the change in levelling point may be measured by the hypsometer (*q.v.*) Many other instruments are also used in surveying; for descriptions of these, works on Surveying must be consulted.

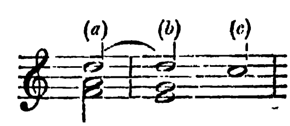
Susceptibility, Magnetic (*Elect.*) The ratio of the induced magnetism in a piece of iron, etc., to the magnetising force. If I be the Intensity of Magnetisation (*q.v.*) and H the magnetising force, the ratio of I to H is termed the MAGNETIC SUSCEPTIBILITY, and usually denoted by the letter k, so that $k = \frac{I}{H}$.

Suspended Coil Galvanometer (*Elect.*) *See* GALVANOMETERS.

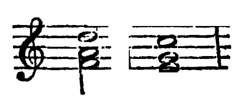
Suspended Magnet Galvanometers (*Elect.*) *See* GALVANOMETERS.

Suspended Solidification (*Chem.*) When a solid has been melted and allowed to stand protected from dust and vibration, it will remain liquid for some degrees below its melting point. This phenomenon is known as suspended solidification: it is a particular case of a perfectly general resistance to change of phase. The liquid will solidify if a trace of the solid is thrown into it, and in doing so its temperature will rise to its melting point. The rate at which the liquid reverts to the solid phase varies with the temperature to which it has been cooled below its melting point, except when it has been very suddenly cooled to a temperature far below this point. In such a case the "liquid" has really become an amorphous solid, which will only revert to the crystalline state very slowly.

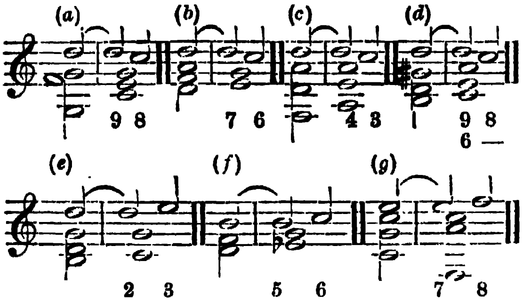
Suspension (*Music*). The holding back of one or more notes whilst the remainder of the chord moves, as



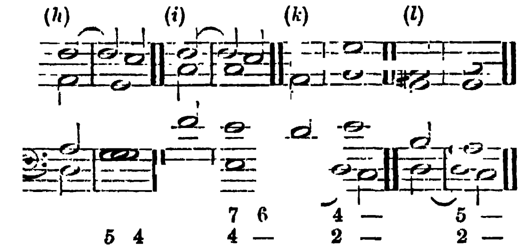
instead of



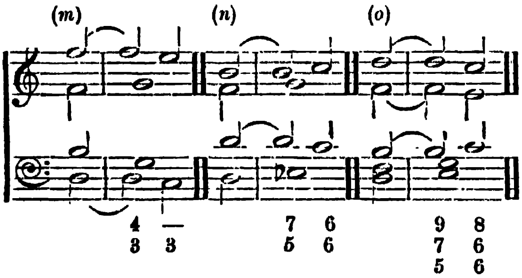
The note D at (*a*) is called the PREPARATION, at (*b*) the PERCUSSION, and at (*c*) the note C is the RESOLUTION. The most usual of the suspensions are the 9-8 (*a*), and its inversion 7-6 (*b*); the 4-3 (*c*) and its inversion (*d*) making a 9-8 over a first inversion; the 2-3 (*e*); the 5-6 over the mediant in the minor key (*f*) also found over the leading note; and the 7-8 (*g*). The last three are sometimes called RETARDATIONS (*q.v.*)



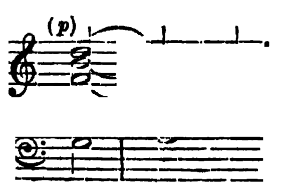
Besides these there are the second inversion of the 9-8 (*h*), making a 5-4 over 6; the second inversion of a 4-3 (*i*) making a 7-6 over 4; the 9-8 in the bass (*k*) and the 4-3 in the bass (*l*).



Two or more of these suspensions may be taken together, as, for instance, the 9th and 4th (*m*), (where the 9th is shown in the bass); the 5th and 7th (*n*); the 9th, 7th, and 5th (*o*). These are known as double suspensions.



There is also the suspension of a complete chord as at (*p*).



See also last four bars of first variation of the Andante of Beethoven's Sonata in G, Op. 14, No. 2. It will be seen that (1) the note or notes suspended are always essential notes of the "preparation" chord, and never of the "percussion" chord; (2) that the suspension moves by step of a second; (3) that the "preparation" chord must not be at a stronger part of the bar than the "percussion" chord. If the preparation is shorter than the percussion, it is better to restrike the suspension than to tie it.

Suspension (*Phys.*) The device by which a light object, such as a galvanometer needle, is supported, so as to be able to turn easily about a given axis. The most usual suspensions are fibres of unspun silk, quartz fibres, and fine wires, or strips, usually of phosphor bronze. The term is also sometimes applied to a support formed by a pivot or a knife-edge.

Suspension Bridge (*Civil Eng.*) A bridge consisting of one large span, or occasionally more, supported at suitable intermediate points by cables or tie rods placed above the roadway, and therefore in tension. The most usual type has a tall tower at (or near) each end of the bridge; between these towers are suspended heavy chains, from which vertical rods are hung to support the bridge proper. The chain is prolonged beyond each tower on the land side, and made fast to the ground by means of masonry, etc., in order to balance the force tending to overturn the tower.

Suspension Links (*Eng.*) Rods or bars by which the slotted link of the LINK MOTION (*q.v.*) in a locomotive, etc., is moved.

Svegliato (*Music*). Awakened.

Swab (*Foundry*). A soft brush or mop used for wetting the parting edge of a mould before the pattern is withdrawn.

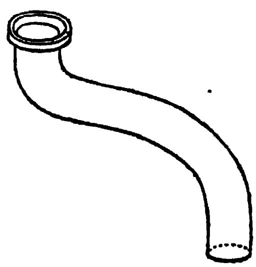
Swage (*Eng.*) A piece of iron or steel of the nature of a die, used in giving some required shape to a forging.

Swage Block (*Eng.*) A large piece of metal containing various holes, grooves, etc., used as swages (*q.v.*)

Swaging (*Eng.*) Shaping a forging by means of SWAGES or dies (*q.v.*)

Swansea (*Porcelain*). A manufactory of earthenware was established at Swansea in 1750. In 1814 Mr. Dillwyn acquired the works and proceeded to make porcelain with the assistance of William Billingsley, who came from Nantgarw. The porcelain was a remarkably fine soft paste, and excellent artists were employed. The manufactory was closed in 1820. The chief characteristics of Swansea porcelain are a fine dark blue and beautifully executed paintings of flowers. *For* MARKS *see under* POTTERY AND PORCELAIN.

Swan's Neck (*Plumb.*) A pipe with a double curve (concave and convex).



SWAN'S NECK.

Swarf (*Chem. Tech.*) The scrapings and chippings from soft iron castings. Used as a reducing agent in aniline manufacture.

—— (*Eng.*) Fine particles of metal, removed by a cutting tool; or particles of sand, etc., worn off a grindstone.

Swash Letters (*Typog.*) The name given to a style of italic capital letters, with tails and flourishes, in vogue in the seventeenth century. Example, *N*.

Swash Plate (*Eng.*) A disc keyed on the end of a rotating shaft in such a way that its plane is not at right angles to the shaft; it is used to communicate a reciprocating motion to a rod which rests on it.

Sweating (*Chem. Tech.*) *See* Manufacture of Paraffin Wax *under* PETROLEUM.

—— (*Eng., etc.*) Joining metal objects by filling in or surrounding the joint with solder and flux and then heating by means of a soldering iron, lamp, or blowpipe until the solder "runs."

—— (*Leather Manufac.*) Hides and skins are hung in a warm damp chamber, and allowed to sweat until the hair or wool is loose enough to be "pulled" or removed. This process is no longer employed in this country for hides, but is largely used in the treatment of sheepskins.

Swedge (*Eng.*) *See* SWAGE.

Swedish Iron (*Met.*) Iron made from certain Swedish iron ores which are very free from sulphur and phosphorus; it is smelted with charcoal, thereby avoiding the introduction of the impurities always found in coal and coke. It is of great value for the manufacture of crucible cast steel, and for the production of soft wrought iron for electrical work (*e.g.* armature and transformer cores).

Sweep. (1) A curve. (2) A curved STRICKLE (*q.v.*)

Sweeping Up (*Moulding*). STRICKING or STRICKLING (*q.v.*)

Sweep Saw (*Carp.*) A COMPASS or PAD SAW, used for cutting curves. *See* SAWS.

Sweet Spirits of Nitre (*Chem.*) *See* ETHYL NITRITE.

Swell (*Cotton Weaving*). A small lever of the third order placed in the shuttle box back of a fast reed loom. The shuttle acts upon it in connection with the shuttle protector.

—— (*Music*). The part of an organ that has the pipes enclosed in a box, called the swell box. *See* MUSICAL INSTRUMENTS, p. 440. The first swell was made by Jordan at the beginning of the eighteenth century.

Swifts (*Woollen Manufac.*) *See* CARDING ENGINE.

Swing (*Eng.*) The swing of a lathe is the radius of the largest piece of material which can be turned in it.

Swing Back (*Photo.*) A frame which is hinged to the camera in such a way that the dark slide and its contained plate can be brought vertical when the camera has to be tilted.

Swing Bridge (*Civil Eng.*) A movable bridge of which the separate parts turn in a horizontal direction, *i.e.* about a vertical pivot or axis. A good example is the swing bridge over the Dee at Hawarden, which is about 285 feet long. The pivot of this bridge is 116 feet from the end, thus dividing it into two unequal parts, of which the longer extends over the channel. A counterpoise weight of over 100 tons is carried by the shorter or tail end, and the total weight of the moving part is 750 tons. This bridge can be opened so as to give an opening of 140 feet in 2½ minutes.

Swiss Machine (*Lace Manufac.*) The usual form of embroidery machine employed in Switzerland and other countries for producing embroidery upon net or other fabric.

Switch (*Civil Eng.*) The device used for effecting a junction of one set of rails with another. *See* RAILWAYS.

—— (*Elect.*) A device for making and breaking the electrical connection in a circuit.

Switchback (*Civil Eng.*) A form of siding used on some American railways in carrying a line up very steep slopes. The line forms a series of zigzags, and at each point where two straight lengths meet is the siding, the lines forming a letter Y. The train is drawn into the tail of the Y, the engine is then attached to the other end, and the train drawn out along the other branch.

Switch Board (*Elect. Eng.*) A support carrying switches, terminals and connectors, and various measuring instruments, by which the connections of a complex system of electric circuits are made and controlled at a Central Station.

Switch, Double Pole (*Elect. Eng.*) A switch which makes and breaks contact in both terminals of an electric circuit. The part of the circuit controlled by the switch is entirely cut off from the remaining or "live" part when the switch is opened.

Switching (*Elect. Eng.*) Operating a SWITCH (*q.v.*)

Switch, Single Pole (*Elect. Eng.*) A switch which breaks the electrical connection in one terminal only of a circuit.

Swivel. (1) A joint hinging or turning on a pin. (2) In gasfitting a joint that will turn horizontally.

Swivel Weaving (*Cotton Weaving*). A method of ornamenting good qualities of cloth by means of a series of small shuttles containing weft of character and colour different from the ground. By this means small weft spots, sprigs, etc., are produced. There are two forms—Horizontal Swivel, Circle Swivel.

Sycamore. *See* WOODS.

Syenite (*Geol.*) A Plutonic rock having granitic structure (*q.v.*), but of a less acid character than granite—*i.e.* containing from 60 to 65 per cent. of silica. A typical syenite contains orthoclase felspar and hornblende, but no free quartz. Varieties, however, occur which contain a little quartz; these are known as QUARTZ SYENITES. Other forms are termed AUGITE SYENITE, MICA SYENITE (or MINETTE), etc., from the presence of these minerals. The name is derived from Syene, in Upper Egypt, where the rock originally termed Syenite occurs; this rock was used in ancient times for architectural and ornamental work.

Sylvanite (*Min.*) A synonym for Graphic Tellurium (*q.v.*)

Sylvine (*Min.*) Potassium chloride, KCl; potassium = 52·5, chlorine = 47·5 per cent. Cubic; colourless or white. One of the salts found in the salt mines of Stassfurt; also as a volcanic product on Vesuvius.

Symbols, Chemical. *See* CHEMICAL SYMBOLS.

Symmetric Planes of a Lens (*Light*). A pair of planes drawn through the SYMMETRIC POINTS (*q.v.*) of a lens, at right angles to the axis.

Symmetric Points of a Lens (*Light*). Two points on the axis of a lens each being at a distance from the nearest Principal Point, equal to twice the Focal Length.

Symmetry. The harmonious proportion or balancing of the parts of a design or body relative to each other.

Sympathetic Inks (*Chem.*) *See* INKS.

Symphony (*Music*). *See* SONATA.

Synchroniser (*Clocks*). A mechanism, generally actuated by an electric current, for making clocks keep identical time. *Cf.* JOURNEYMAN.

Synchronising (*Phys.*, *Elect. Eng.*, *etc.*) The regulation of two (or more) machines or pieces of apparatus so that their movements or effects produced by them occur simultaneously: *e.g.* two alternators which are to be run in parallel must produce currents which not only possess the same frequency, but the same phase (*q.v.*), so that their maxima and minima occur at identical times.

Synchronous Charts (*Meteorol.*) Charts which present the principal elements of the weather at any given instant.

Synchronous Motor (*Elect. Eng.*) An alternating current motor which must keep in phase with the alternating current which drives it. Its speed is therefore absolutely fixed by the frequency of the supply. *See* MOTORS, ELECTRIC.

Syncline or **Synclinal Structure** (*Geol.*). Strata bent into a trough-like form, so that the beds dip towards the axis about which the folding has occurred. *Cf.* ANTICLINAL.

Syncopation (*Music*). A false accent produced by prolonging a note begun on an unaccented part of a bar over a more accented part. It is generally marked by an accent >.

Synodic Month (*Astron.*) The interval of time between one conjunction (*q.v.*) of the moon and the succeeding one.

Synodic Period (*Astron.*) The time in which a planet returns to the same position with regard to the sun and earth.

Synoptic Charts (*Meteorol.*) *See* SYNCHRONOUS CHARTS.

Synthesis (*Chem.*) The building up of a compound from its elements. Thus, when hydrogen burns in oxygen, water, which is the product of the combustion, is built up from its elements or synthesised. In speaking of the synthesis of organic compounds—say, for instance, of glucose and indigo—when the chemist says that these have been synthesised, he really means that if it were necessary they could be built up from their elements: for in such cases the starting point for the synthesis is a fairly complex body, which could, if required, be made from its elements. Glycerine and naphthalene are substances which could be made on a large scale from their elements, but the processes would be long and costly; nevertheless, as glucose and indigo respectively can be artificially made from these, they are said to have been synthesised. Before a compound can be synthesised, its constitution must be known; then, as a rule, the compound can be synthesised; but even then a synthesis may prove exceedingly difficult; the constitution of camphor was known long before it could be synthesised.

Syphon. *See* SIPHON.

Syren. *See* SIREN.

System (*Geol.*) A group of formations (*q.v.*) which occur in association with one another, and which contain a closely related set of fossils; *e.g.* the CRETACEOUS SYSTEM, including the Chalk, Greensands, and the Wealden Rocks. *See also* STRATA, TABLE OF (*in Appendix*).

Systems of Crystals (*Min.*) A crystal system is a group of crystals, all the members of which have certain similar properties as regards the lengths and mutual inclinations of their axes, and as regards symmetry of form. If a comparison be made of the lengths of the axes cut off by the several planes of a crystal (the INTERCEPTS of these planes), it is found that these lengths bear a definite and comparatively simple relation to one another. Suppose a certain plane is found to cut off, on three axes meeting in a common point called the Origin, three unequal lengths, a, b, c; the intercept of other planes on these three axes taken in the same order are found to bear to a, b, c, some such simple relation as a, b, $3c$, or $2a$, $2b$, $5c$, or $\infty\, a$, b, c. Then the lengths a, b, c, are called the PARAMETERS of the crystal, and it is these parametral lengths which have to be considered in classifying crystals according to their systems. It is found that all crystal forms of one mineral have intercepts on the axes which can be expressed in simple integral terms (positive or negative, and including zero and infinity) of a, b, c, the integral numbers in most cases not being higher than 7. The intercept of a plane on one of the axes may seemingly be a fraction of the parametral length, as $\frac{a}{2}$, b, $2c$, but since for crystallographic purposes planes that are parallel and on the same side of the origin are identical, these intercepts can be expressed as a, $2b$, $4c$.

Since the parametral lengths are taken as units once their values are determined, the intercepts of any plane may be stated by using the numerators of a, b, c; *e.g.* in the above instance the intercepts can be expressed by *1 2 4*. But it is usual to employ the reciprocals of the intercepts as the *Index* of a form; hence the plane in question would be designated *4 2 1*, the whole numbers proportional to $\frac{4}{4}, \frac{2}{4}, \frac{1}{4}$ or $\frac{1}{1}, \frac{1}{2}, \frac{1}{4}$.

The symmetry of a crystal depends on the possible number of planes along which the crystal may be divided into symmetrical portions.

There are six crystallographic systems, as tabulated below (some of the more common synonyms of each system being given):—

I.	II.	III.
Cubic	Tetragonal	Hexagonal
Isometric	Dimetric	A. Hexagonal Division
Monometric	Quadratic	
Regular	Pyramidal	B. Rhombohedral Division
Tesseral		

IV.	V.	VI.
Rhombic	Monosymmetric	Triclinic
Trimetric	Monoclinic	Asymmetric
Orthorhombic	Oblique	Doubly Oblique
Prismatic	Clinorhombic	Anorthic

I. CUBIC SYSTEM. Three axes (a) of equal length and at right angles. There are three equal planes

of symmetry having their intersections in the lines of the three axes, and six diagonal planes of symmetry equal in themselves.

II. Tetragonal System. Three axes at right angles, the two horizontal ones (a) being equal, and the vertical one ($\acute{c}$) being either longer or shorter than the others. There are three planes of symmetry intersecting in the axes, two of them equal, and two diagonal planes equal to one another.

III. Hexagonal System. This includes (A) the Hexagonal group proper, and (B) the Rhombohedral division.

In (A) there are three axes (a) of equal length inclined to one another at 60°, and a third ($\acute{c}$) vertical to the plane of the others through the origin. The vertical axis may be longer or shorter than the others. There are four axial planes of symmetry, three equal radial planes and a horizontal plane unequal to the others. There are also three diagonal planes equal in themselves.

In (B) the axes may be regarded as only three in number, equal and inclined to one another at equal angles, and lying in the three radial symmetrical planes of the hexagonal division. There are three planes of symmetry, intersecting at 120° to the vertical and coinciding with the three radial axial planes of the hexagonal division. Rhombohedral forms may be regarded as hemihedral forms (those with only alternate faces developed) of the hexagonal group. A hemihedral form of the rhombohedral group would correspond to a tetartohedral of the hexagonal (the fourth face only being developed).

IV. Rhombic System. Three axes at right angles, $\breve{a}$, $\bar{b}$, $\acute{c}$, all unequal, and three planes of symmetry intersecting in these axes and all unequal. The right-and-left axis is called the Macrodiagonal, and is designated by $\acute{b}$ and is always taken equal to unity. The front-and-back axis is the brachydiagonal, a; it is less than unity. The vertical axis is $\acute{c}$.

V. Monosymmetric System. Three unequal axes, $\grave{a}$, $\acute{b}$, $\acute{c}$, the two lateral axes being at right angles to one another, but only $\acute{b}$, the orthodiagonal, is at right angles to the vertical axis $\acute{c}$, the clinodiagonal, $\grave{a}$, being inclined to $\acute{c}$ at an angle β. The axis $\acute{b}$ is taken as unity, and $\grave{a}$ is usually less than $\acute{b}$, but not necessarily so. There is only one plane of symmetry, the plane containing $\grave{a}$ and $\acute{c}$.

VI. Anorthic System. Three axes, a, b, $\acute{c}$, all unequal and all inclined to one another, the angle between b and $\acute{c}$ being α, that between a and $\acute{c}$ being β, and that between a and b being γ. In this system there is no plane of symmetry, opposite pairs of faces being only symmetrical with regard to the point called the origin.—W. G.

Systyle (*Architect.*) The name given to the arrangement of the columns in a Grecian temple when the space between the columns is equal to twice the lower diameter of the shaft. *See* Aræostyle, Pycnostyle, Diastyle, *and* Intercolumniation.

Syzygy (*Astron.*) One of the two opposite positions of an orbit which a celestial body is in at Conjunction (*q.v.*) or at Opposition (*q.v.*), *e.g.* the points occupied at new and full moon.

Ta (*Chem.*) The symbol for Tantalum (*q.v.*)

Taa (*Architect.*) *See* Pagoda.

Tabard (*Her.*) A garment shaped something like an overall, reaching nearly to the knee, open at the sides, and with wide sleeves or flaps reaching to the elbows. Worn originally over body armour and generally emblazoned with the arms of the wearer or his lord. Subsequently adopted as a general article of dress. In England the tabard is now worn only by heralds and pursuivants of arms, and bears the arms of the sovereign. *See* Coat Armour.

Tabaret *or* **Taborette** (*Silk Manufac.*) A fabric consisting of alternate stripes of watered tabby (*q.v.*) and satin.

Tabby *or* **Taffeta** (*Silk Manufac.*) A plain fabric formed by the simplest kind of weaving, being always one thread up and one thread down all over—*i.e.* each alternate thread of the warp being raised and the intermediate threads depressed for the first pick, the action on the warp threads being reversed for the second pick.

Tabby Tie (*Silk Weaving*). *See* Tie.

Tabernacle (*Architect.*) (1) The ciborium or baldachino (*q.v.*) over an altar. (2) A canopied niche or stall. The carved openwork used in these canopies is known as Tabernacle Work.

Table (*Eng., etc.*) A horizontal plate on which pieces of material are laid or fixed while being operated upon, *e.g.* the term is commonly applied to the part of a drilling or planing machine which supports the work.

—— (*Gems*). (1) The plane or large flat facet on the top of a brilliant-cut stone. (2) A stone of oval, round, square, oblong, or other form, cut flat on the upper and lower sides, which are bordered by rows of square or triangular facets.

—— (*Glass Manufac.*) The term applied to the circular plate of glass (about 54-70 in. in diameter) which forms the final product in the manufacture of Crown Glass (*q.v.*)

—— (*Math., etc.*) A series of numbers or other quantities arranged in a form convenient for reference—*e.g.* in parallel columns.

—— (*Music*). The upper surface of the board, above the channels of the sound board, in an organ. *See* Musical Instruments, *p.* 439.

—— *or* **Tablet** (*Architect.*) A flat slab or surface usually of rectangular shape, such as a monumental slab. A Raised Table projects from the wall face, and a Raking Table is one which is not vertical.

Table Scarf (*Carp. and Join.*) A scarf joint having a flat surface notched into another piece end to end.

Tablet (*Archæol.*) One of a set of thin plates of wood, ivory, or other material, hinged together, and used for writing upon. The surface of the tablet was coated with a thin layer of wax, which was protected by a raised edge, and the writing was effected by means of a style (*q.v.*)

Table Vice (*Eng.*) A light vice attached to a bench.

Table Work (*Typog.*) Matter consisting of figure work, etc., composed of five columns or more. If with headings four columns or more. *Cf* Tabular Work.

Tablinum (*Architect.*) An apartment in which records were stored in a Roman house. It was situated between the atrium and the peristylium.

Taborette (*Silk Manufac.*) *See* Tabaret.

Tabular Spar (*Min.*) A name for WOLLASTONITE (*q.v.*)

Tabular Work (*Typog.*) Figure work, etc., consisting of three or four columns. *Cf.* TABLE WORK.

Tacet (*Music*). An indication that a certain voice or instrument so marked is to be silent.

Tacheometer (*Surveying*). An instrument for the indirect measurement of distances. The eyepiece of its telescope is furnished with two horizontal cross wires, the arrangements being such that the distance of a vertically held staff, called the stadia (*q.v.*), is determined at once by viewing the latter through the telescope and noting the number of divisions on the staff seen between the cross wires.

Tachometer *or* **Tachymeter** (*Eng.*) A speed indicator; an apparatus for measuring the number of revolutions per minute of some rotating part of a machine.

Tachylite (*Geol.*) A glassy lava of basic composition, *i.e.* corresponding in composition to Basalt (*q.v.*)

Tackle (*Eng.*) A rope or chain and pulley block, or a combination of chains and ropes and pulley blocks, working together and used for lifting heavy weights.

Tackler (*Cotton Manufac.*) An overlooker who keeps the looms in repair and performs other functions necessary to keep them running.

Tacks (*Plumb.*) The ears attached to lead pipes by which they are fixed to the wall.

Tacky (*Dec.*) A condition which is reached when a coat of paint or varnish is not quite dry. This condition is ascertained by placing the finger lightly against the paint or varnish, which will adhere to it slightly if tacky. Paint and varnish sometimes remain tacky for a considerable time owing to an excess of driers, a dirty, greasy surface, or to the varnish having been applied where there is lack of proper ventilation. When gold size (*q.v.*) is used as a medium by which to cause gold leaf to adhere to the letters of a sign or other surface, the gold size is painted on and is allowed to become just tacky before the gold leaf is applied. *See* DRYING OF PAINT, DRYING OILS, *and* VARNISHES.

Tænia *or* **Tenia** (*Architect.*) The fillet on the upper edge of the Doric architrave. *See* DORIC ORDER; ARCHITECTURE, ORDERS OF; *and* ENTABLATURE.

Taffeta (*Silk Manufac.*) *See* TABBY.

Taft Joint (*Plumb.*) A blown joint (*q.v.*)

Tail (*Bind.*) The bottom edge of a book, including paper and cover.

—— (*Build.*) The lower or exposed part of a roofing slate or tile.

—— (*Eng.*) The lower or hinder part of various machines, *e.g.* the vertical rod or support of a fitter's vice.

Tail Bay (*Carp. and Join.*) The end bay of a roof or ceiling.

Tailings (*Leather Manufac.*) Tan liquor that has become "sour."

—— (*Mining*). The refuse material or worthless slimes (*q.v.*) that are rejected in washing an ore that has passed through the stamp mills. The tailings are sometimes subjected to further treatment for the extraction of metal they may contain.

Tail of a Comet (*Astron.*) The stream of light which commonly accompanies a bright comet. The tail is always turned away from the sun.

Tail Piece (*Music*). That part of stringed instruments to which the strings are attached at the lower end.

Tail Pieces (*Typog.*) Ornaments placed in a short page at the end of a chapter, article, or volume, to fill up the vacancy.

Tail Race (*Eng., Mining, etc.*) The race or channel which leads the waste water away from a water wheel or other machinery.

Tail Stock (*Eng.*) The movable head or poppet of a lathe (*q.v.*)

Tail Vice (*Eng.*) The large vice (*q.v.*) used by fitters, blacksmiths, etc.; it has a vertical rod or column, termed the tail, resting on the floor of the workshop.

Tail Water (*Eng.*) The waste water flowing away from a water wheel.

Take (*Typog.*) When copy (*q.v.*) is apportioned to the compositors to be set up in type, the portion falling to each compositor is termed a "take."

Taker Off (*Print.*) The person who releases the printed sheet from the printing press or machine.

Taking Off (*Build.*) Taking measurements from drawings.

Taking Up (*Eng.*) Shortening or tightening fittings, moving parts, etc., which have become elongated or loosened by wear.

—— (*Textile Manufac.*) A motion for automatically winding the cloth as it is woven on to a cloth roller. *See* LOOM.

Taking Up Slack (*Eng.*) Shortening a belt or chain which has become elongated.

Talaria (*Art*). The sandals or greaves, ornamented with wings, which are characteristic of the attire of Hermes (Mercury), Eros, and certain other divinities in classical mythology.

Talc (*Min.*) A hydrous silicate of magnesia. Silica = 62, magnesia 33·1, water 4·9 per cent.; 1 or 2 per cent. of iron and a little alumina often occur as well. Crystals are rhombic, but the mineral is usually found massive, and is easily split into thin plates, which are distinguished from those of Mica (*q.v.*) by not possessing elasticity. Colour white, light or dark green. Common in many localities.

Talking Machine. *See* PHONOGRAPH.

Tallboy (*Build.*) A long chimney pot made of zinc or iron.

Tallow Cup (*Eng.*) A lubricator holding tallow.

Talus (*Geol.*) Débris produced by weathering, which accumulates in sloping heaps at the foot of a cliff.

Tamarind (*Botany*). The fruit of *Tamarindus indica* (*Leguminosæ*) in the form of a preserve is used in pharmacy either alone or in combination with other substances. Its properties are laxative and refrigerant.

Tambourine (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 445.

Tamping (*Met., etc.*) Stopping up a vent or tap hole in a furnace by means of clay.

—— (*Moulding*). Ramming the sand round a pattern.

Tan. The abbreviation used for TANGENT: *see* TRIGONOMETRICAL RATIOS.

—— (*Leather Manufac.*) *See* LEATHER MANUFACTURE.

Tanagra Figurines (*Archæol.*) Small terracotta figures representing divinities and incidents of Greek domestic life, etc. They were usually cast, and after being baked were generally brilliantly coloured. Used as household ornaments and as votive offerings; some of the earliest examples are from the cemetery of Tanagra in Bœotia.

Tandem (*Cycles*). A cycle carrying two riders, one behind the other. Machines of the same type carrying three or four riders, termed TRIPLETS and QUADRUPLETS, are little used except in pacing a racing cyclist.

Tandem Engine *or* **Pump** (*Eng.*) An engine or pump having two (or more) cylinders arranged in the same straight line with one piston rod running right through and carrying all the pistons. *See* STEAM ENGINE.

Tanekaha (*Botany*). A New Zealand pine tree, *Phyllocladus trichomanoides* (order, *Coniferæ*), whose bark, known as Tanekaha, is used in tanning, and as a dye for leather.

Tang (*Carp., etc.*) The pointed end of a tool such as a chisel or gouge, which is driven into the wooden handle.

Tangent (*Math.*) (1) The tangent to a curve is a line touching the curve, but not cutting it. (2) A Trigonometrical Ratio (*q.v.*)

Tangent Galvanometer (*Elect.*) *See* GALVANOMETERS.

Tangent Screw. A screw whose point acts on a radial arm or other device attached to some portion of an instrument or machine in order to obtain an angular motion of small amount; in some cases the screw gears directly into a worm-wheel mounted on the axle of the rotating part. Tangent screws are fitted to spectroscopes, theodolites, and many astronomical instruments.

Tangent Spokes (*Cycles*). Spokes which leave the hub at a tangent to its rim, instead of radially. They are stronger and also easier to replace if broken than "direct" or radial spokes.

Tank (*Civil Eng.*) A reservoir, whether artificially constructed throughout or formed by utilising a natural hollow or depression.

Tank Base (*Eng.*) A hollow casting serving as the baseplate of an engine, etc., and also as a tank or reservoir; *e.g.* in the case of oil engines a considerable supply of oil is often contained in a tank of this kind.

Tank Engine (*Eng.*) A small locomotive carrying a supply of water in a tank fitting over or placed alongside the boiler.

Tank Liquor (*Chem.*) *See* ALKALI.

Tan Liquor (*Leather Manufac.*) A general term used to denote all solutions of the various tanning materials used in the tanyard. *See* LEATHER MANUFACTURE.

Tannic Acid (*Chem.*) *See* TANNINS.

—— (*Eng.*) This acid is used to prevent incrustation of boilers; it forms insoluble compounds with salts of lime, and this can be removed in the form of a scum by blowing off (*q.v.*)

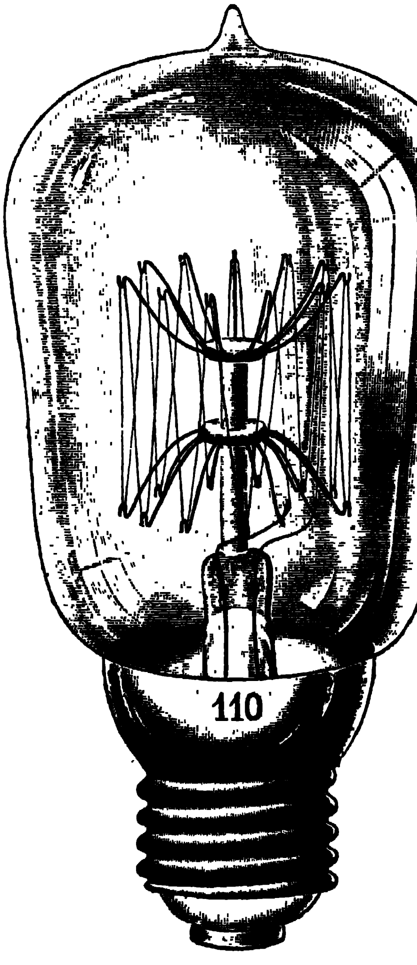
Tanning. *See* LEATHER MANUFACTURE.

Tannins (*Chem.*) Substances of unknown constitution which occur widespread in the vegetable kingdom, have an astringent taste, are soluble in water, their solutions are precipitated by lead acetate, and give a dark blue or green colouration with iron salts. Many give precipitates with gelatine and convert skins into leather; some are glucosides of gallic acids, while others are compounds of phloroglucin and gallic acid. Examples: TANNIC ACID (gallotannic acid: tannin), is nearly colourless when pure, but usually it is met with as a brownish yellow powder; when heated it darkens in colour and gives pyrogallic acid and carbon dioxide. It is soluble in water, giving a dextrorotatory solution; when an alkali is added to the solution, it rapidly absorbs oxygen and turns black. Its solution is easily hydrolysed to gallic acid (*q.v.*) by acids, alkalis, and certain ferments; it reduces Fehling's solution and ammoniacal silver; with iron salts it forms ink; it precipitates gelatine, albumin, starch, the alkaloids; it also gives precipitates with tartar emetic, lead acetate, and a number of other salts. Tannic acid is used as an astringent in medicine, in making ink, in the preparation of gallic and pyrogallic acids, and as a mordant in dyeing. It occurs in gallnuts from various kinds of oak, in sumach, and in tea. It is extracted from finely ground gallnuts by a mixture of aqueous alcohol and ether: the extract separates into two layers, the lower layer containing the tannic acid, which it yields on evaporation. CAFFETANNIC ACID is the tannin found in coffee berries; its solution does not precipitate gelatine, and it gives a green colour with ferric chloride; it is a glucoside. QUERCITANNIC ACID occurs in oak bark and probably in tea.

Tantalum (*Chem.*) Ta. Atomic weight, 183. A rare metal, when pure resembling platinum in colour: melts between 2,250° and 2,300°; sp. gr. 16·5; malleable and very ductile. Its tensile strength is about the same as that of steel, the breaking load for a wire of 1 mm. diameter being 93 kilos. When a lump of tantalum is heated to redness and brought under the steam hammer, it forms a plate which when repeatedly treated in the same way becomes so hard that a diamond will not bore it. The specific resistance for a wire 1 metre long and 1 mm² section is 0·165 ohms. The temperature coefficient is ·003 between 0° and 100°, and between 0° and 350° it is ·0026, and at a consumption of 1·5 watts per candle power it reaches 0·855 ohms. On account of its high melting point and its resistance to "dusting" and its smaller energy consumption per candle power (a carbon filament uses 3·5 watts per candle power), tantalum has been applied to the construction of electric lamps. The figure shows a lamp which gives 24 to 27 candles at 110 volts and 0·35 amperes; the wire is 0·05 mm. in diameter and 650 mm. long; it gives a bluish white light. When heated in air, tantalum begins to oxidise, turning yellow at 400° and ultimately giving the white pentoxide; it absorbs hydrogen readily and nitrogen on heating; it does not amalgamate with mercury. When heated and thrown into water, it decomposes it. It is not attacked by acids except hydrofluoric, which attacks it slowly; aqueous alkalis do not attack it even on boiling.

Tantalum belongs to Group V. of the Periodic system, and is allied to vanadium and niobium; it occurs with niobium in tantalite, columbite, pyrochlor, and yttrotantalite. The metal is obtained by heating

sodium or potassium tantalofluoride with sodium; the powdery metal so obtained is pressed to coherent masses and heated in the electric arc in a vacuum, when the metal melts to a platinum-like regulus.



To obtain the tantalofluoride, finely powdered tantalite is fused with acid potassium sulphate, the melt extracted with water, and the insoluble part digested with ammonium sulphide; the residue is washed and boiled with dilute hydrochloric acid; the insoluble part is washed, dissolved in hydrofluoric acid, filtered, and heated to drive off silicon fluoride, and potassium fluoride added. On concentrating potassium tantalofluoride, K_2TaF_7, crystallises out first. Two oxides of tantalum are known, a tetroxide, Ta_2O_4, and a pentoxide Ta_2O_5—the latter is obtained by heating potassium tantalofluoride with concentrated sulphuric acid, extracting the potassium sulphate with water, and heating the insoluble tantalum sulphate. The chloride, $TaCl_5$, crystallises in yellow needles; melts at 211°; boils at 242°; sublimes below its melting point; it fumes in air, and water converts it into tantalic acid, $HTaO_3$.

Tanto (*Music*). Too much; as much as.

Tap (*Eng.*) (1) A cock. (2) A tool used for cutting internal or female screw threads. A FIRST TAP, ENTERING TAP, or TAPER TAP is a steel screw or external thread, with flutings or grooves (usually three in number) cut across the thread parallel to the axis of the screw in order to present a series of cutting edges; towards the point the thread is gradually removed, so that the diameter of the tool is reduced at the end till it is sufficiently small to enter a TAPPING HOLE (*q.v.*) drilled to receive it. After the tapering tap has roughed out the thread in the hole, a SECOND TAP with somewhat less taper may be passed through, and the thread is finally finished off with a parallel tap the full size of the required thread, termed a PLUG TAP. For making dies (*see* STOCKS AND DIES) a tap somewhat similar to a Plug Tap is used: this is termed a MASTER TAP, HOB, or HUB. The flutings of a master tap are narrower and more numerous than those of an ordinary tap.

—— (*Met.*) To tap a furnace is to open the TAP HOLE, an opening through which the molten metal flows.

Tape (*Build., Eng., etc.*) A measuring tape may be made either of a woven fabric or of a thin steel band; the latter is much preferable, as a woven tape stretches considerably with use, and becomes inaccurate.

Taper. A gradual slope or a diminution in diameter. Applied especially to the narrowing of a pattern, in order to enable it to be withdrawn easily from a mould. The part of a deep pattern which is uppermost in the mould, and which is withdrawn first, may be from one-eighth to a quarter of an inch wider than the lowest part.

Tapered Pipe (*Build.*) A stoneware drain pipe with one end smaller than the other.

Taper Screw Chuck (*Eng., etc.*) A chuck consisting of a small disc, in the centre of which is a coarse-threaded tapering screw, like an ordinary wood screw, by means of which a piece of wood can easily be attached to the chuck for turning.

Taper Tap (*Eng.*) The tap first used to form the thread in tapping a hole. *See* TAP.

Taper Turning (*Eng.*) Turning a conical surface. Usually effected either by setting the back centre out of the axial line of the lathe, or by using a slide rest with one of its slides set at the necessary angle to the bed of the lathe.

Tapestry. An ornamental textile fabric used for covering walls and furniture, or for hangings. The fabric is composed of coloured wools and silk, other materials, *e.g.* gold thread, being sometimes introduced. The method of manufacture is practically that of the Oriental carpet, the design being effected entirely by the weft, which is inserted by means of wooden needles or spindles termed "broaches," the whole of the operations being carried out from the back of the warp. Tapestry may be divided into two classes: (1) High Warp, in which, during manufacture, the warp is stretched vertically, with a roller or cylinder at each end; (2) Low Warp, in which the work is carried on with the warp in a horizontal position. The first method is generally employed for high class pictorial work; the second for the production of less intricate designs, though in the finished state it is difficult to distinguish the fabrics. In the fourteenth century some Flemish towns, notably Arras, were noted for their fine tapestries, hence the name "arras" eventually became synony-

mous with "tapestry." The Bayeux Tapestry (*q.v.*) is really an embroidered roll of linen. South Kensington Museum contains a very fine collection of tapestry.

Tape Worms (*Hygiene*). Parasites which affect man and food animals, chiefly under the forms of *Tæina solium*, *T. mediocanellata*, and *T. echinococcus*. *See* PARASITES.

Tap Grooving (*Eng.*) Cutting the flutings or grooves in a tap (*q.v.*) Usually performed by a rotary cutter.

Tap Hole (*Met.*) *See* TAP.

Taping (*Elect. Eng.*) Covering a conductor, etc., with tape, which forms part of the insulating or protecting covering.

Tapioca (*Foods*). A farinaceous substance prepared from the roots of the plant *Cassava*, the name given to several species of *Manihot* (*q.v.*), which grow in tropical America and elsewhere. The granules resemble those of sago, but are considerably smaller. Certain poisonous qualities of the root are removed by washing and heating the pulp.

Tappet (*Eng.*) An arm, cam, collar, or lever projecting from some movable part of a machine in such a manner that the motion of that part of the machine brings it in contact intermittently with some other part to which it communicates an intermittent motion.

—— *or* **Eccentric** (*Weaving*). A shedding motion produced in the power loom by means of mechanism termed variously cams, eccentrics, tappets, or wipers, and suitable shafts or levers which are connected with the healds or heddles. (*See* LOOM.) The motion is employed for weaving the simplest forms of plain cloth. *Cf.* DOBBY *and* JACQUARD. In the woollen trade the two chief types of tappet loom are (1) the Woodcroft, in which the shafts are both lifted and depressed positively; (2) the Yorkshire, in which the lifting motion is positive and the depressing negative. In the cotton trade the chief types are (1) box tappets; (2) sections; (3) oscillating; (4) cams. Some of these are positive and some negative in action.

Tapping (*Eng.*) Cutting an internal screw thread by means of a TAP (*q.v.*)

—— (*Met.*) Opening the tap hole (*q.v.*) of a furnace to allow molten metal to flow out.

Tapping Hole (*Eng.*) A hole in which an internal thread is to be cut. It is drilled out so that its diameter is less than that of the screw which has to fit into it by twice the depth of the thread; this leaves sufficient metal to form the internal thread, the grooves being formed by means of the thread on the tap. *See* TAP *and* TAP WRENCH.

Tap Wrench (*Eng.*) A two-handled lever or bar, used for turning a tap (*q.v.*) It usually has a medial hole which fits the squared head of a tap, different sizes being used according to the size of the tap. Some forms, however, have adjustable clamping pieces, by means of which taps of various sizes can be actuated by the same tap wrench.

Tar. A black viscid product of very mixed composition, resulting from the dry distillation of certain natural organic substances. Not very long ago tar was produced solely from wood. At the beginning of the nineteenth century, however, tar began to be made from coal, and more recently petroleum tar has been added to the list. Wood tar and gas tar are dealt with separately; but attention is directed to the general resemblance existing between the methods and results of the dry distillation of coal and that of wood. This resemblance affords an additional argument in favour of considering coal to be of vegetable origin, although the fact is proved without this assistance. In both cases there are three distinct products of the distillation—*viz.* gas and two liquids—one watery, the other dark and thickly flowing. In both the nature of the distillate, although, of course, depending upon the kind of substance distilled, is also largely influenced by the temperatures used and by the rate at which the temperatures are arrived at. Again, although there are many substances produced by coal distillation which are absent from the distillate obtained from wood and *vice versâ*, the two distillates contain many substances in common.

WOOD TAR.—This is prepared as a by-product in the manufacture of charcoal. When wood is burnt in the open air in "meilers," the tar sweats out, and is collected in receptacles placed underground near the meiler. On the other hand, when wood is charged in retorts, the tar is collected in receivers exactly as coal tar or any other distillate is collected. The wood is heated either by direct fire or by superheated steam. Both the yield and the composition of the distillate depend upon the sort of wood used and the other conditions above referred to. Coniferous wood gives more tar than others, and is used for the purpose when it ceases to yield turpentine. With slow distillation coniferous wood gives from 9 to 14 per cent., and other woods from 5 to 11 per cent. The tar separates by gravity from the weak aqueous solution containing acetic acid and spirit among other things which accompany it, as it is heavier than water, having a specific gravity averaging from 1·1 to 1·2. It happens sometimes, however, that untapped trees of certain resinous conifers are distilled into tar. In this case the turpentine, which also comes over, dissolves the tar into a liquid which is lighter than water, and therefore forms the upper instead of the lower layer. It is used as produced, or after a second distillation, for waterproofing and preserving ropes and timber. It is unaffected by water as regards its main constituents, and it contains creosote, which is a powerful antiseptic. The tar usually retains some of the crude acetic (pyroligneous) acid formed in the distillation of the wood, an amount varying from 5 to 15 per cent. according to the distillation and the sort of wood used. This is removed by neutralisation with lime, and the remaining tar will give on distillation from 5 to 15 per cent. of "light oils," from 15 to 20 per cent. of "heavy oils," and from 35 to 60 per cent. of non-volatile residue known as pitch. The pyroligneous acid is used for several purposes. For example, it serves to make impure acetates used by dyers in mordanting, but it is also rectified for the production of pure acetic acid. The methyl alcohol separated out during this process is used for denaturating or methylating spirits of wine. The light oils contain benzole and toluol, and can be used in dye manufacture. The most important constituents of the heavy oils are paraffin, creosote, and guiacol. The two last are extensively used in pharmacy, and creosote, which consists principally of carbolic and cresylic acids, is extensively employed for waterproofing timber. The residual pitch of the distillation is used as a protection against water, being painted or poured over the surface to be protected while hot and liquid. Its constitution is complicated and imperfectly known;

but it may be regarded as a mixture of heavy oils which have resisted the temperatures employed in the distillation with free carbon obtained by the charring of the less volatile distillates. The uses of paraffin are chiefly for candle making and as an insulator in electrical appliances.

COAL TAR.—The use of coal tar dates necessarily from the introduction of coal gas, and for a long time it was only obtained as a by-product of the manufacture of that gas. Large quantities are now obtained, however, from the coke ovens in which coke is prepared from coal for metallurgical purposes, when the gas is used to help heat the ovens; and still more from the gases escaping from blast furnaces, which are, of course, huge gas retorts. The present annual production of coal tar in England has been estimated at 650,000 tons from gas works, 150,000 from blast furnace gases, and 62,000 from coke ovens. Coal tar is a black, viscid liquid having a specific gravity of from 1·1 to 1·2. It sinks below the watery distillate (which is now the source of all the ammonia and ammonia salts of commerce) in the gas main, and the two liquids are drawn off separately from time to time. Like wood tar, coal tar is extraordinarily complex in its constitution. It is a mixture of certainly more than a hundred different substances. It will be gathered from what follows that it is a much more valuable commercial product than wood tar. The composition of the tar is regulated by the same circumstances as that of wood tar; but in general the substances constituting it may be classified under the following three heads: Hydrocarbons, nitrogenous bodies, and alcohols (phenol and its homologues). The most important hydrocarbons are benzole, naphthalene, anthracene, phenanthrene, and chrysene (*q.v.*) The nitrogenous bases include aniline, quinoline, and pyridine, and the most important alcohols are phenol, naphthol, and cresol. The tar is distilled in enormous stills, in some of which forty tons can be heated at one time. Disregarding the minor fractionations which are carried out in practice, the distillates may be divided into three main portions: FIRST RUNNINGS and LIGHT OILS come over up to 210° C., and form from 3 to 8 per cent. of the tar. They contain benzole and toluol. When the temperature has reached 210° the CARBOLIC OILS begin to come over. They constitute from 16 to 20 per cent. of the tar, and are replaced between 270 and 400° by the anthracene oils. The carbolic oils contain phenol (carbolic acid), cresol, and naphthalene; while of the anthracene oils, which also form from 16 to 20 per cent. of the tar, the most valuable constituent is anthracene. There is a final residue of about 50 per cent. of pitch, which has the same uses as wood pitch. The various volatile constituents are separated by fractionating separately the different distillates obtained in the first crude distillation, advantage being taken of the differences in their boiling points. The uses of the coal tar products are so well known that only a passing reference to them is required. The huge dye-making industry, which employs hundreds of thousands of persons, draws nearly all its raw materials from coal tar. Hardly less important is the manufacture of drugs, such as phenacetine, antipyrine, etc., and of photographic developers, such as metol and many others, from coal tar. Carbolic acid and cresol are well known as among the most valuable and widely used disinfectants; and lastly, it should be mentioned that some of the nitrogenous bases, such as pyrol and pyridine, are coming into use for methylating spirit, as they give a liquid which cannot be fraudulently renaturated, as is possible with ordinary methylated spirit.—A. S. J.

Targe *or* **Target** (*Arm.*) A small shield of circular form; a buckler. The term was applied generally in the seventeenth century to any form of shield used by an infantry soldier as a substitute for body armour.

—— (*Her.*) A charge representing a circular shield.

Tarsia. A kind of mosaic woodwork forming a panel; a style of decoration in vogue in Italy in the fifteenth century. The designs often comprised architectural features, foliage, and even landscapes, and were effected by means of various woods either naturally or artificially shaded.

Tartan (*Textile Manufac.*) A fabric, originally produced in the Highlands of Scotland, of a plaid or check pattern.

Tartar Emetic (*Chem.*) $\left\{\begin{array}{l} CHOHCOOSbO \\ | \\ CHOHCOOK \end{array}\right\}_2 H_2O$ or

$\left\{\begin{array}{l} CHOHCOO \\ | \\ CHOHCOO \end{array}\!\!\!>Sb\,.\,OK\right\}_2 H_2O$ (Potassium antimonyl tartrate). Colourless rhombic octahedra, which effloresce on exposure to air; soluble in water (1 part in 15 parts at 15°). Poisonous, but in small doses it acts as a sudorific; in larger doses as an emetic. Its solution gives a precipitate with tannic acid; it also decolorises a solution of iodine (basis of estimation). It is prepared by boiling 4 parts antimony trioxide, 5 parts cream of tartar, and 50 parts water, filtering if necessary, and allowing to stand till crystallisation occurs.

Tartaric Acid (*Chem.*) $\begin{array}{l} CHOHCOOH \\ | \\ CHOHCOOH \end{array}$ (Dioxysuccinic acid.) As this compound contains two asymmetric carbon atoms having the same radicals attached to each, it can occur in a dextrorotatory form, in a lævorotatory form, and in two inactive forms, one due to internal compensation (mesotartaric acid), and the other due to a combination of equal quantities of the two active forms (racemic acid). *See* STEREOISOMERISM. ***Dextrotartaric acid*** is the ordinary tartaric acid. Colourless monoclinic prisms; melts at 153°, or 167°-170° if rapidly heated; very soluble in water (138 in 100 parts at 15°); soluble in alcohol (20·4 parts in 100 at 15°); the aqueous solution is dextrorotatory, the specific rotation varying with the concentration. When heated with water (10 parts acid to 1 part water), it is changed to a mixture of racemic acid and mesotartaric acid; at 165° little of the former and much of the latter, while at 175° the reverse is the case. A solution of tartaric acid prevents the precipitation of hydroxides from salts of copper, iron, aluminium, and many other metals by alkalis. On careful oxidation it yields dihydroxytartaric acid (*q.v.*); powerful oxidising agents give carbon dioxide and water. When tartaric acid is dry distilled, it yields among other products pyrotartaric acid (*q.v.*) and pyruvic acid (*q.v.*) On reduction with hydriodic acid it yields first malic acid, then succinic acid. Ammoniacal silver nitrate oxidises tartaric acid (its salts), on warming, to carbon dioxide and oxalic acid. *See* SILVER. Tartaric acid occurs chiefly as acid potassium tartrate (cream of tartar), especially in grape juice; on fermentation the tartrate is deposited after a time, and the crude deposit is

called argol, or, after recrystallisation, tartar; when crystallised till pure the product is called CREAM OF TARTAR. This salt also occurs in many common fruits and vegetables, such as cucumbers, berries of mountain ash, mulberries, sorrel. The acid also occurs in the same things as calcium salt, but in much smaller amount. On the large scale tartaric acid is obtained from argol by adding water and boiling by steam, then adding powdered chalk:

$$2KH\bar{T} + CaCO_3 = Ca\bar{T} + K_2\bar{T} + H_2O + CO_2.$$

The calcium tartrate is filtered off, and the solution of potassium tartrate precipitated by calcium chloride (or gypsum):

$$K_2\bar{T} + CaCl_2 = Ca\bar{T} + 2KCl.$$

The whole of the calcium tartrate is washed and decomposed by warm dilute sulphuric acid, the calcium sulphate filtered off and washed, and the filtrate concentrated in steam-heated leaden pans to crystallisation. The coloured crystals are dissolved in hot water, decolorised by animal charcoal, and again crystallised with addition of a little sulphuric acid. For medicinal purposes the product is recrystallised. Synthetically dextrotartaric acid is obtained by the resolution of racemic acid into its components; the racemic acid is made into sodium ammonium racemate, and the solution of this salt slowly crystallised. Crystals with right and left hand hemihedral faces separate, which can be separated by hand. On making each into the lead salt and decomposing the latter by sulphuretted hydrogen, the dextrohemihedral crystals give dextrotartaric acid and the others lævotartaric acid. This was the first instance of the resolution of an optically inactive substance into its active components, and the resolution was effected (1847) by Pasteur at the age of twenty-five. Racemic acid can also be resolved by combining it with a number of active alkaloids—*e.g.* with quinine, in which case the salt of dextrotartaric acid crystallises first. *Lævotartaric acid* is similar to dextrotartaric acid, except that the crystalline form is the mirror image of that of the dextro acid, and its solution is lævorotatory. It is obtained, as described above, from racemic acid: and when a solution of racemic acid is fermented with penicillium glaucum, the dextro acid is destroyed, while the lævo acid remains. RACEMIC ACID forms triclinic prisms containing one molecular proportion of water of crystallisation, which it loses at 100° to 110°; melts at 205°; less soluble in water than tartaric acid; its solution is optically inactive; chemically it behaves like tartaric acid, but on reduction with hydriodic acid it gives inactive malic acid. It is formed by the union of equal quantities of the dextro and lævo acids with evolution of heat, and from tartaric acid as before mentioned. Synthetically it can be obtained from fumaric acid by oxidation with potassium permanganate: along with mesotartaric acid, from the silver salt of dibromsuccinic acid by boiling it with silver oxide and water,

$$\begin{array}{l}CHBrCOOAg\\ |\\ CHBrCOOAg\end{array} + 2AgOH = \begin{array}{l}CHOHCOOAg\\ |\\ CHOHCOOAg\end{array} + 2AgBr,$$

and also along with mesotartaric acid from glyoxal by the series of reactions indicated in the scheme:

$$\begin{array}{l}CHO\\ |\\ CHO\end{array} \xrightarrow[HCN]{} \begin{array}{l}CH<^{OH}_{CN}\\ |\\ CH<^{CN}_{OH}\end{array} \xrightarrow[H_2O]{} \begin{array}{l}CH.OH.COOH\\ |\\ CH.OH.COOH.\end{array}$$

MESOTARTARIC ACID. This compound is inactive by internal compensation. *See* STEREOISOMERISM. Crystallises in rhombic tables with one molecular proportion of water of crystallisation; melts at 140°; soluble in water (125 parts in 100 parts at 15°); obtained from dextrotartaric acid as before mentioned, and separated by converting the product into the acid potassium salts, of which the mesotartaric is very soluble in water, while the dextrotartrate is very sparingly soluble, also from the mixtures of mesotartaric and racemic acids by conversion to the calcium salts, of which calcium mesotartrate is the more soluble, also from maleic acid by oxidation with potassium permanganate. TARTRATES. *Acid potassium tartrate*, or cream of tartar, $\begin{array}{l}CHOHCOOH\\ |\\ CHOHCOOK\end{array}$ crystallises in rhombic prisms; sparingly soluble in water (1 part in 200 parts at 15°), less soluble in alcohol. Can be prepared from tartaric by dividing a given solution of the acid into two equal parts, exactly neutralising one part with caustic potash, and then adding the other part; on the large scale, as before mentioned. It is used in making black flux, in dyeing, and in medicine. *Sodium potassium tartrate* (Seignette's salt, or Rochelle salt); rhombic prisms; soluble in water; obtained by neutralising cream of tartar with sodium carbonate. Used in silvering glass (*see* SILVER), and in medicine. *Calcium tartrate*, $\begin{array}{l}CHOHCOO\\ |\\ CHOHCOO\end{array}\!\!>Ca$, crystallises in rhombic prisms containing four molecular proportions of water when calcium chloride is added to a neutral solution of a tartrate; very sparingly soluble in water (1 part $Ca\bar{T},4H_2O$ in 6,265 parts water at 15°); soluble in alkaline tartrate solution, and in caustic soda or potash. *Potassium antimony tartrate*. *See* TARTAR EMETIC.

Tartrates (*Chem.*) Salts of TARTARIC ACID (*q.v.*)

Tartrazine (*Chem.*, *Dyeing*). *See* DIHYDROXYTARTARIC ACID.

Tar Well (*Gas Manufac.*) *See* GAS MANUFACTURE.

Tassets (*Arm.*) A pair of metal appendages, often jointed and flexible, which hung from the cuirass or corselet to protect the thighs in front. Worn during the fifteenth, sixteenth, and seventeenth centuries.

Tasto Solo (*Music*). Implies that the notes are to be played without accompanying harmonies.

Taurine (*Chem.*) $\begin{array}{l}CH_2NH_2\\ |\\ CH_2SO_2OH\end{array}$ (Amidoisethionic acid). Colourless monoclinic prisms; melts with decomposition about 240°; soluble in water, insoluble in alcohol. It behaves as a weak acid. Nitrous acid converts it into isethionic acid $\begin{array}{l}CH_2OH\\ |\\ CH_2SO_2OH.\end{array}$ Taurine occurs free in bile, but chiefly in combination with cholalic acid as taurocholic acid. The latter yields taurine on hydrolysis.

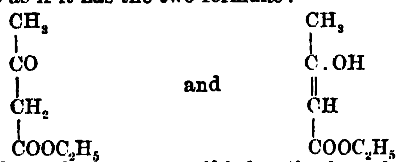
$$C_{26}H_{45}NO_7S + H_2O = \begin{array}{l}CH_2NH_2\\ |\\ CH_2SO_2OH\end{array} + C_{24}H_{40}O_5.$$

Taurine can be obtained from ox-bile by adding hydrochloric acid, filtering, and concentrating when a resinous mass separates; the aqueous solution is

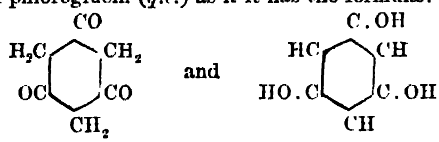
poured off, further concentrated, filtered, and the taurine precipitated by alcohol; it is recrystallised from water.

Taurocholic Acid (*Chem.*) $C_{26}H_{45}NO_7S$. Needles; very soluble in water and in alcohol, less soluble in ether; when boiled with water it is hydrolysed. *See* TAURINE. The solution is dextrorotatory. It occurs as the sodium salt in bile; to obtain it bile is precipitated with lead acetate, which separates glycocholic acid, filtered, and the filtrate precipitated by basic lead acetate. The lead taurocholate thus precipitated is decomposed by sulphuretted hydrogen.

Tautomerism (*Chem.*) Many substances are known which react as if they possess more than one formula. For example, ethyl acetoacetate (*q.v.*) reacts as if it has the two formulæ:

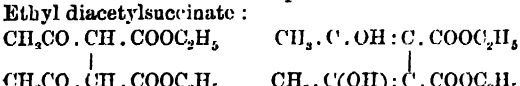


and phloroglucin (*q.v.*) as if it has the formulæ:



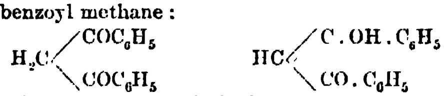
while 1-phenyl-3-methyl-5-pyrazolone (*see* PYRAZOLE AND ITS DERIVATIVES) can react as if it has three formulæ. To this phenomenon many names have been given, such as Tautomerism, Pseudomerism, Desmotrophy. Of these, perhaps the commonest is the first one. In the above examples, although the substances react as if they have more than one formula, they are only known in one form; but in some cases the so-called tautomers are known in more than one form. Examples of such are:

Ethyl diacetylsuccinate:

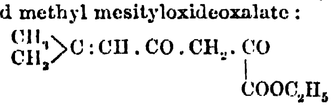


Keto form (two solid forms). M.Ps. 68° and 88°. Enol form (liquid).

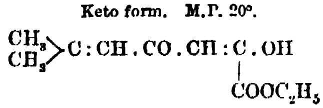
Debenzoyl methane:



Ethyl and methyl mesityloxideoxalate:

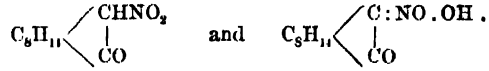


Keto form. M.P. 20°.

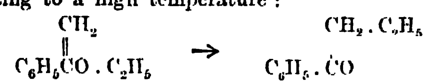


Enol form. M.P. 59°—60°.

We will illustrate the relations between the two forms a little more fully in the last case. The enol form goes over into the keto form on prolonged heating on the water bath; the keto form passes in part into the enol form on prolonged heating at 130°; the enol form shows the higher refractive and dispersive power for light. In this case, on solution the enol appears to pass entirely into the ketol, but the solvent exercises a great influence on the speed, ionising solvents bringing about the change far more rapidly than non-ionising—thus in chloroform the change is very slow, in benzene and carbon disulphide it is slow, but in methyl and ethyl alcohol the change is rapid. Thus it must be assumed that in these cases ionisation occurs. With some tautomers equilibrium between the two forms occurs on solution; this is the case with nitrocamphor, which is a solid, and only known in one form in the solid state, but, as the change of rotatory power on solution shows, it must be present in solution in two forms—the normal form and pseudo form:



The determination of which of the possible formulæ of a tautomeric substance is to be assigned to it is carried out by physical methods; examples of such determinations are given under MOLECULAR MAGNETIC ROTATION, MOLECULAR REFRACTIVE POWER, SPECTRUM ANALYSIS. It will be seen from the foregoing that tautomerism is nothing more than ordinary isomerism between substances which can pass somewhat readily into each other; that is to say, no very sharp line of demarkation exists between tautomerism and ordinary isomerism. Most tautomeric compounds contain a mobile hydrogen atom. When the mobile group is complex, the change of one tautomer into the other becomes more difficult to effect; this isoacetophenone ethyl ether is only changed into phenylpropyl ketone on prolonged heating to a high temperature:



When the two tautomeric forms can exist in equilibrium with each other, the phenomenon is called by some chemists "dynamic isomerism." A method of determining the point of equilibrium in such cases has been devised by Lowry; it depends on the measurement of the solubility of one of the isomers, or better, when the substance is optically active, of the change in rotation which occurs on solution, for the two forms will not have the same specific rotatory power. Suppose a tautomeric substance A to be known in one form only; let it be dissolved in a solvent in which the change into the form B is not quick—say it takes days. Determine its solubility at once by thoroughly shaking an excess of A with the solvent until the latter is saturated, and then finding how much is dissolved in a given weight of the solvent. Now set aside a part of the saturated solution in contact with excess of A; as A transforms into B, more of A will go into solution, and this will continue until equilibrium is established between A and B in solution and between the solid and liquid phases of A. Determine the solubility under the new conditions, and it is clear that if α is the first solubility and β the second, we have equilibrium between α of A and $(\beta - \alpha)$ of B. A similar argument holds for the change in specific rotation.

Tawing (*Leather Manufac.*) The process of dressing skins for glove leather by means of alum, salt, flour, and egg.

Tazza. A large shallow ornamental cup or bowl, mounted on a foot and generally having two handles.

T-Bolts *or* **Tee Bolts** (*Eng.*) Bolts with large heads (usually rectangular), forming a T. They are used in the tee slots (*q.v.*) of machine tables.

Te (*Chem.*) The symbol for Tellurium (*q.v.*)

Tea (*Foods*). Tea consists of the dried leaves of a shrub, *Thea sinensis*, grown in China, Japan, India, and Ceylon. Green tea differs from black solely in the method of preparation, the former being dried over wood fires when fresh, the latter being dried slowly over charcoal fires after lying in heaps (withering) for about twelve hours. Tea contains albumin, extractives (about 15 per cent.), dextrine, mineral salts, tannin (about 13 per cent.), oil, and an alkaloid known as thein (about 3 per cent.) Tea should be made with boiling water and not allowed to stand longer than five minutes, otherwise the quantity of tannin extracted renders the infusion astringent and unwholesome. If soft water be used a less quantity of tea is required. As a beverage tea is valuable as a nervous stimulant; but the abuse of it leads to a weakened digestion, constipation, and sometimes nervous depression. *See* FOODS.

Teak. *See* WOODS.

Teazing (*Woollen Manufac.*) The operation of mixing the wool prior to carding (*q.v.*)

Technique (*Arts*). The mastery of detail and the qualities of hand and eye that result in technical and manipulative skill.

Tedge (*Foundry*). A GATE or RUNNER (*q.v.*)

Tee Bolt, etc. *See* T-BOLT.

Teeming (*Met.*) Pouring out molten metal. Used especially by the steel makers in the North of England.

Tee Slots (*Eng.*) Slots formed on the surface of the table of a planing machine or slotting machine, etc., in order to hold the heads of Tee Bolts: the cross-section of the slot is in the shape of a T, and of such a size that the bolt can be inserted at one end, and then moved along it to any point at which an object has to be bolted to the table.

Telamones (*Architect.*) *See* ATLANTES.

Telegraph and Telegraphy. The simplest form of telegraphic apparatus consists in principle of a galvanometer (the RECEIVING INSTRUMENT or RECEIVER) connected by an insulated wire (the LINE) to a battery and to a transmitting key, or TAPPER, placed at a distant station; the circuit is usually completed through the earth, to which both ends of the system are connected. By means of the transmitting key an operator can cause a current to flow in either direction at will, thus producing a deflection of the receiving needle either to the right or the left. The instrument can thus transmit two distinct signals, which may be combined together in any manner desired, *e.g.* to produce an alphabet and other signals desired; the combination of signals in general use is that known as the Morse Alphabet or Morse Code.

The two signs used are generally represented as a dot and a dash, and the alphabet is formed as follows:

A • —	J • — — —	S • • •
B — • • •	K — • —	T —
C — • — •	L • — • •	U • • —
D — • •	M — —	V • • • —
E •	N — •	W • — —
F • • — •	O — — —	X — • • —
G — — •	P • — — •	Y — • — —
H • • • •	Q — — • —	Z — — • •
I • •	R • — •	

Other combinations of dots and dashes are used to indicate figures, and also certain other signs and abbreviations.

The single needle instrument may be replaced by one with two needles; or an instrument may be used in which a sound is produced by the motion of an armature attracted by an electro-magnet. By employing an instrument which can give two distinct sounds, or by using long or short intervals between successive sounds, the two signals necessary for the MORSE CODE can be obtained. The receiving operator reads the message by ear alone, and can write it down as it is received. When the line is of great length, and the transmitted currents are feeble, either a very sensitive receiving instrument is used, or a relay (*q.v.*) is fitted to the receiving instrument, which is then actuated by a local battery, the feeble current in the line being utilised to actuate the relay.

The above instruments have the two great disadvantages that no permanent record of the messages can be obtained, and that the speed of transmitting is very limited. Both these defects are overcome in printing or writing instruments. In these the current actuates an instrument which can make a mark upon a long strip of paper drawn through the receiver by mechanism. To obtain the two distinct signals; the marks may be made short and long ("dot and dash") as in the Morse Printing Telegraph, or a continuous line may be produced, which remains straight so long as no current is sent through the receiver, but is bent into a sinuous form if the writing device be deflected to one side or the other by the action of the current. The Kelvin Siphon Recorder is of the latter type, the line being drawn by ink flowing from the end of a fine tube, bent into a siphon, and dipping into a reservoir of ink. The deflection of the siphon is produced by a coil suspended between the poles of a magnet, the passage of a current through the coil causing it to turn, as in the D'Arsonval Galvanometer. Increased speed is attained by a mechanical method of transmission. A strip of paper is perforated with holes arranged to correspond with the dots and dashes of the Morse code, and the strip is then drawn through a transmitting instrument so constructed that a hole in a particular position causes the circuit to be completed and a current sent through the line. The strips are perforated by a machine worked by hand, but a long message may be prepared by employing a number of operators simultaneously, the strips being afterwards passed through the transmitter in succession. By this means the speed of transmission may be increased ten-fold or even more, a matter of great importance when a number of lengthy messages have to be sent over a given system. In a recently invented form of writing telegraph the record is obtained by the action of a beam of light on a strip of sensitised paper, which is afterwards developed and fixed; the deflection of the beam is produced by the movement of a very small mirror, such as is used in reflecting galvanometers. The moving parts are very light, and the necessary motion very small, so that the mirror responds very rapidly to a very small current. With this telegraph, developed by Virak and Pollak, the extraordinary speed of 1,000 words per minute is said to have been attained. Printing telegraphs have also been devised to record the message in ordinary characters; they may be roughly described as electrically worked typewriting machines, in which a keyboard at one station actuates printing mechanism at another by means of an electric current.

LAND LINES, or the wires used for ordinary telegraphy on land, are usually of bare iron wire, having a resistance of about 16 ohms per mile; they are attached to insulators of earthenware, carried on the cross bars on the poles. But the use of underground wires is increasing, owing to frequency of breakdowns in aerial wires through storms and other causes. Such wires are necessarily coated with insulating substances, and further covered with some material to protect them from the action of water. SUBMARINE CABLES require still further protection, and are usually surrounded by a sheath of wires, covered with hemp and guttapercha.

The testing of the wires forms a very important branch of the telegraphist's work, and breakages, contact between two lines, a complete or a partial connection to earth, can all be detected and the position of the fault found by an operator perhaps many miles away. Many of the methods employed depend on the accurate measurement of resistances, the form of Wheatstone's Bridge (*q.v.*) termed the Post Office Box being largely used in this connection. The electrical capacity of a system is also in certain cases a guide to the detection of a fault.

DUPLEX telegraphy consists in sending messages along a single wire in both directions at the same time; in the commonest case this is effected by connecting the instruments and the line to the earth by suitably adjusted resistances, forming a combination of conductors resembling that of a Wheatstone Bridge. In DIPLEX working two messages may be sent simultaneously in the same direction, special instruments being used which only act when the current flows through them in one direction. In QUADRUPLEX telegraphy, two messages may be sent each way simultaneously, a combination of the DUPLEX and DIPLEX methods being employed.

Telegraphy, Wireless (*Elect. Eng.*) *See* WIRELESS TELEGRAPHY.

Teleiconograph. An instrument consisting of a combination of the telescope and the camera lucida (*q.v.*), invented by M. Révoil. The camera lucida is attached to the eyepiece of the telescope in such a manner that an image of objects coming within the field of view appear to the observer to be projected on a sheet of paper placed below the eyepiece so that the outline can easily be sketched. The scale of the drawing depends on the distance the paper is placed from the eyepiece.

Telemeter (*Surveying*). An American term for the stadia (*q.v.*)

Telephone. One of the most typical forms of telephone is that of Bell. This contains a thin circular plate or diaphragm of iron, supported at its circumference; a bar magnet is placed with its axis at right angles to the diaphragm, and one pole placed opposite and close to the centre. A coil of fine wire surrounds the magnet, being placed close to the same pole. When sound waves fall upon the diaphragm the latter is caused to vibrate, and as the iron approaches or recedes from the pole of the magnet, induced currents are set up in the coil of wire. If the latter be connected by wires to the coil of a similar instrument or RECEIVER placed at a distance, the induced currents, in flowing through the second coil, will set up vibrations in the diaphragm of the receiver, which correspond very closely to those of the first or "transmitting" diaphragm, and the original sounds will be closely reproduced. This instrument is now used chiefly as a receiver, and in many cases the original form is very closely adhered to. Its use as a transmitter was, however, abandoned at an early date, and a different form of instrument substituted for this purpose, by which the effects were very greatly improved. Modern transmitters are based upon the principle of the MICROPHONE (*q.v.*) The original microphone of Hughes was a light pointed rod of carbon, supported loosely in a vertical position between two carbon blocks; the instrument was connected in series with a battery and a telephone receiver, and the current entered the microphone by one block, passing through the carbon rod and the two loose contacts, and left by the other block. No sound is heard in the receiver so long as the current is steady; but a very minute movement of the carbon rod causes a variation of the resistance of the circuit, and a corresponding alteration of the current, which produces a movement of the diaphragm of the receiver, and consequently a sound. The vibrations of the receiving diaphragm are much stronger than the original ones, and sounds as minute as those produced by a fly walking over the base board of the microphone, are distinctly heard on the telephone. In modern transmitters, the sound impinges on a metal diaphragm, behind which lie loose carbon contacts, often in the form of small grains; the electrical connections follow the same principle as in the original instrument.

The action may be improved in long lines by the insertion of a small induction coil in the circuit. The transmitter and battery are included in the primary coil, and the secondary coil, which has a much larger number of turns of wire, is connected in series with the transmitting wires or "telephone line," and with the receiver. By this means a much higher voltage, and consequently a stronger current, is obtained in the receiving circuit than would be the case if the coil were not used.

A simple form of telephone "set" consists of receiving and transmitting instruments, a call-bell, and a bell-push by which the bell at the receiving end of the line can be rung: the induction coil and battery may also be included. The receiver when not in use is hung from a lever forming part of a switch, which connects the line to the call bell, so that the latter can be rung to attract attention; on removing the receiver from its support, the lever rises and operates the switch in such a way that the line is disconnected from the bell, and connected to the receiver itself, so that a message spoken into the transmitter at the other end can now be heard.

Inter-communication between different subscribers is effected by means of an EXCHANGE; a subscriber first "calls up," or gets into communication with, an operator at the exchange. The signal necessary to attract the operator's attention is either given by means of a bell, or the mere act of removing the receiver from its support may automatically supply the signal at the exchange, either by actuating a bell or lighting up a small glow lamp; the operator then connects up the first subscriber's instrument to that of the second subscriber whose number is quoted, by means of a switch board to which the necessary wires are attached. The arrangements of the wires and switch boards are very ingenious, but too complex for a brief description.

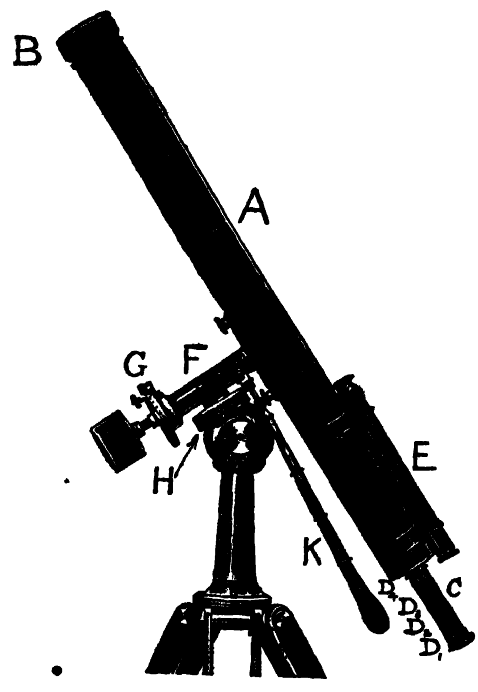
Telescope. An optical instrument by which an image of a distant object is produced, this image being viewed through a magnifying eyepiece. Telescopes may be divided into two classes, according to the means employed to produce the image. In Class 1, REFRACTING TELESCOPES, the image is pro-

duced by a lens termed the OBJECT GLASS or OBJECTIVE; in Class 2, REFLECTING TELESCOPES, the image is produced by a concave mirror of large radius, termed a SPECULUM.

(1) The object glass of a refracting telescope is an achromatic lens of long focus, which produces a real, inverted, and diminished image of the object observed. In the ASTRONOMICAL TELESCOPE this image is viewed through a lens or system of lenses acting as a simple magnifying glass, which produces a vertical, magnified, and inverted image; the inversion is, however, of no moment in astronomical work. A TERRESTRIAL TELESCOPE possesses an erecting eyepiece, usually consisting of four similar planoconvex lenses, separated by distances depending on their varying foci. GALILEO'S TELESCOPE, which forms the optical system of a modern OPERA GLASS, possesses a concave eye lens, which is placed between the object glass and the image produced by the latter. By this means an erect and magnified image is produced.

(2) Reflecting telescopes possess several distinct advantages, especially for astronomical work. They can be made of much greater aperture than refracting telescopes; chromatic aberration is entirely absent, and spherical aberration is avoided by making the speculum parabolic instead of spherical in form. The mirror may be constructed of glass, ground to shape and silvered; or of speculum metal (an alloy of copper and tin), which is capable of receiving a high polish on its surface. Reflectors differ in the method employed for viewing the image. In HERSCHEL'S TELESCOPE the axis of the mirror is inclined so as to throw the image to the side of the tube, the eyepiece being suitably placed to receive the image. In NEWTON'S TELESCOPE a small plane mirror is placed inside the tube, so as to receive the rays after reflection from the speculum, and reflect them again towards the eyepiece, which is placed at the side of the telescope and directed towards the plane mirror. In GREGORY'S and CASSEGRAIN'S TELESCOPES there is a small curved mirror placed axially inside the telescope tube. This receives the rays after reflection from the speculum, and reflects them back through a central aperture in the speculum; the eyepiece is placed so as to receive the rays through this aperture.

MOUNTING OF TELESCOPES.—Terrestrial telescopes require nothing more than a tripod stand which supports the telescope at a convenient height and enables it to be turned in any required direction by means of a suitable joint. Astronomical telescopes have much more elaborate forms of mounting, depending on the special purpose for which the instrument is required. The TRANSIT CIRCLE consists of a telescope mounted on a horizontal axis pointing due east and west and carrying a vertical graduated circle; the telescope therefore always lies in the meridian. For observations of bodies not on the meridian, and for continuous observations, other forms of mount are necessary. The ALTAZIMUTH instrument has two axes, one vertical (the PRIMARY AXIS), the other (or SECONDARY AXIS) being horizontal, and carried by the former. Each axis carries a graduated circle by which it can be brought into any position, or the angle through which it has been turned read off. An EQUATORIAL instrument has also two axes, the secondary being horizontal, but the primary one is inclined so as to point in the direction of the pole. This axis carries a graduated circle termed the HOUR CIRCLE, while the horizontal axis carries what is termed the DECLINATION CIRCLE. The figure represents a small portable Equatorial by Dollond; the object glass is of 3 in. aperture and 3 ft. 6 in. focal length.



A is the body or tube of the telescope; the object glass is at B; C is the eyepiece (a terrestrial eyepiece is shown in the figure, the four lenses being placed at D_1, D_2, D_3, D_4). E is the FINDER (*q.v.*) The primary axis is at F, inclined so as to point in the direction of the pole. The graduated circles are shown at G and H. The telescope is turned while a star is being observed by means of the handle K, so that the object always remains in the field of view.

Various accessories are used with astronomical telescopes, such as a FINDER (*q.v.*), VERNIERS, and READING MICROSCOPES for determining the exact angular position of the instrument by reading the graduated circles; TANGENT SCREWS for effecting small or gradual movements of these circles; CROSS WIRES in the eyepieces; some arrangements for illuminating the wires; and many other devices. Devices are also used for photographing celestial bodies, and for observing their spectra, but these do not form part of the telescope proper.

Telescopic Pipes (*Eng., etc.*) Pipes which slide into one another at the joints, like the tube of a pocket nautical telescope, so as to admit of a certain amount of lengthening or shortening. They are often used in pumping water from coffer dams, mine shafts, etc.

Telescopic Shaft (*Eng.*) A shaft constructed in a similar manner to a telescopic pipe to allow of longitudinal extension.

Telescopic Stars (*Astron.*) Stars that are invisible to the naked eye, and require a telescope to observe them. *Cf.* STAR MAGNITUDES.

Telespectroscope (*Astron.*) A combination of telescope and spectroscope for analysing the light of the celestial bodies.

Tell Tale (*Eng.*) An indicator used to show when a certain number of revolutions has been made by a machine, *e.g.* a WINDING ENGINE (*q.v.*); also similar automatic devices used in various machines to indicate the completion of a certain series of movements.

—— (*Music*). In organs the weight suspended from the bellows, which falls and rises as the reservoir fills and empties. One is generally in view of the organist and another in view of the blower, when blown by manual labour.

Telluric Bismuth (*Min.*) Telluride of bismuth; sulphur and selenium are also present in some cases. Hexagonal system. Colour pale grey. Found in Cumberland, Norway, Sweden, Hungary, United States, etc.

Tellurium (*Chem.*) Te. Atomic weight, 127·6. A lustrous white metal (or metalloid) belonging to Group VI. of the Periodic system; melts at 452°; boils at 478° in the vacuum of the kathode light; it can be distilled in a current of hydrogen, and may be purified in this way; crystallises in rhombohedra. Its vapour density corresponds to the formula Te_2. Tellurium burns with a blue flame when heated in air to the dioxide; it is soluble in a concentrated solution of caustic potash, forming a red solution which contains potassium telluride and potassium tellurite; nitric acid oxidises it to tellurous acid. Tellurium occurs free, and as graphic tellurium (Ag . Au) Te_2 (*q.v.*), as nagyagite $(Au . Pb)_3(Te . S . Sb)_3$ (*q.v.*), as silver telluride (Ag_2Te), and as bismuth telluride (Bi_2Te_3). It can be obtained by boiling the ore with concentrated sulphuric acid, diluting the solution, and adding hydrochloric acid; gold and silver are thus separated, and on passing sulphur dioxide into the clear solution tellurium is precipitated. For a purer product the whole operation is repeated; it may be further purified as indicated above. When precipitated from its solution by sulphur dioxide, the tellurium is in an amorphous condition. Radioactive tellurium is the name given to the deposit formed when bismuth is immersed in a solution which contains polonium. *See* RADIUM. This deposit consists chiefly of tellurium, and is strongly radioactive, but the activity is not due to tellurium, for the latter can be precipitated from the active solution in an inactive state. TELLURIDES. Telluretted hydrogen, H_2Te, is a colourless gas; boils at 0°; melts at ·48°; it has an offensive odour like sulphuretted hydrogen, and is soluble in water. It is very readily decomposed; light decomposes it, and it is partly decomposed on heating $TeH_2 \rightleftarrows Te + H_2$; it is also decomposed on contact with moist air. Telluretted hydrogen precipitates tellurides from salt solutions like sulphuretted hydrogen precipitates sulphides. The gas is obtained, mixed with hydrogen, by the action of a dilute acid on magnesium or zinc telluride; or in nearly pure condition by electrolysis of 50 per cent. sulphuric acid at −15° to −20°, using tellurium as kathode. Metallic tellurides are obtained by heating the corresponding elements together; the alkaline tellurides can also be obtained by passing telluretted hydrogen into a solution of the alkaline hydroxide. CHLORIDES. The dichloride $TeCl_2$ is a black solid which melts at 175° and boils at 327°, giving a vapour which has a characteristic absorption spectrum; it is decomposed by water: $2TeCl_2 + 3H_2O = Te + H_2TeO_3 + 4HCl$. It is formed by heating tellurium in chlorine, boiling the product with more tellurium, and distilling. The tetrachloride, $TeCl_4$, is a white crystalline solid; melts at 224°, and boils at 380°; it is deliquescent, and decomposed by water, giving an oxychloride and tellurous acid in the cold, the latter alone on boiling. It is prepared by heating tellurium in excess of dry chlorine. OXIDES. Tellurium dioxide, TeO_2, is a white crystalline solid, practically insoluble in water; it dissolves in caustic soda or caustic potash, forming tellurites Ne_2TeO_3 and K_2TeO_3; it is formed by burning tellurium or by dissolving it in nitric acid and crystallising above 20°. Tellurium trioxide, TeO_3, is an orange yellow crystalline solid; when strongly heated it gives the dioxide; water does not act on it. Boiling concentrated caustic potash gives potassium tellurate; boiling hydrochloric acid gives telluric acid and chlorine. It is prepared by heating telluric acid. ACIDS. Tellurous acid, H_2TeO_3, is a white amorphous solid, sparingly soluble in water, more soluble in acids; on heating, it readily yields the dioxide; it is a feeble acid, and dissolves in alkalis forming tellurites; potassium permanganate oxidises it to telluric acid. Tellurous acid is obtained by dissolving tellurium in nitric acid and immediately adding much water when the acid is precipitated. Telluric acid, H_6TeO_6, crystallises in white monoclinic prisms; soluble in water; it is a feeble acid; it dissolves in alkalis forming tellurites; it is reduced to tellurium by sulphur dioxide and many other reducing agents. It is prepared by dissolving tellurium in a mixture of nitric and chromic acids, crystallising the solution, washing the crystals with nitric acid and dissolving them in water, reprecipitating with nitric acid, and finally crystallising from water. SALTS. No well-defined normal salts in which tellurium acts as a metallic radical are known, so that tellurium has more of the characteristic reactions of a non-metal than a metal. Tellurites (*see* above) are known, and tellurates. Potassium tellurate, $K_2H_4TeO_6 3H_2O$, may be prepared by fusing the dioxide with caustic potash and potassium chlorate; on adding barium chloride to its solution, barium tellurate, $BaH_4TeO_6 . H_2O$, is precipitated. This barium salt is far more soluble in water than barium sulphate.

Tellurium (*Min.*) The metal has been found native, but is very rare; it usually occurs in combination as a telluride.

Temper (*Eng.*) The hardness, elasticity, and other conditions produced in steel by certain operations of heating and cooling. *See* TEMPERING.

Temperament (*Sound*). A modification of the pitch of the notes forming the scale, which enables notes belonging to one key to be used as part of the scale of another key. Consider the succession of notes forming the natural scale, or, as it is termed, a scale with JUST INTONATION: then taking the frequency of the tonic or key note as unity, the frequencies of the remaining notes are as follows:

C	D	E	F	G	A	B	C′
1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2

Taking these notes in pairs it is found that the intervals, or the ratios of the frequencies of two successive notes, are not constant, but that there are three different intervals or ratios; thus the interval between the first two notes is $\frac{9}{8}$, between the second two $\frac{10}{9}$, and between the third two, $\frac{16}{15}$. The complete scale therefore contains the following intervals:

$$C \underbrace{\ \ }_{\frac{9}{8}} D \underbrace{\ \ }_{\frac{10}{9}} E \underbrace{\ \ }_{\frac{16}{15}} F \underbrace{\ \ }_{\frac{9}{8}} G \underbrace{\ \ }_{\frac{10}{9}} A \underbrace{\ \ }_{\frac{9}{8}} B \underbrace{\ \ }_{\frac{16}{15}} C'$$

The interval $\frac{9}{8}$ is termed in Acoustics a MAJOR TONE, $\frac{10}{9}$ a MINOR TONE, and $\frac{16}{15}$ a LIMMA. The major and minor tones are very nearly equal; the ratio between

them is $\frac{9}{8} \div \frac{10}{9}$ or $\frac{81}{80}$; this interval is termed a COMMA. Suppose we take a scale in which C has a frequency of 270; the other notes will then have the following frequencies:

$$\begin{array}{ll} C' & 540 \\ & \quad \tfrac{16}{15} = \text{limma} \\ B & 506\tfrac{1}{4} \\ & \quad \tfrac{9}{8} = \text{major tone} \\ A & 450 \\ & \quad \tfrac{10}{9} = \text{minor tone} \\ G & 405 \\ & \quad \tfrac{9}{8} = \text{major tone} \\ F & 360 \\ & \quad \tfrac{16}{15} = \text{limma} \\ E & 337\tfrac{1}{2} \\ & \quad \tfrac{10}{9} = \text{minor tone} \\ D & 303\tfrac{3}{4} \\ & \quad \tfrac{9}{8} = \text{major tone} \\ C & 270 \end{array}$$

This scale will be perfectly correct so long as we keep to the key of C; but if we attempt to change the key, *i.e.* to take any other note than C as the key note, we shall meet with certain difficulties. Suppose D be taken as the key note; the first interval will be a minor tone, instead of a major tone, while the next interval will be a limma, when it ought to be a minor tone, an interval nearly twice as great. The latter difficulty is met by introducing a new note between F and G, which we term "F sharp" (F♯). There exists, however, no practical method by which the first difficulty can be surmounted. A compromise is therefore effected by which the relative frequencies of the notes are so adjusted that they may be utilised in the scale of other keys with equal, or approximately equal, accuracy; this compromise is termed Temperament. There are many possible temperaments, which it is not possible to discuss here (*see* A. J. Ellis, "Proceedings of the Royal Society," vol. xxiii. pp. 3-31), but the most important is that known as EQUAL TEMPERAMENT. In this, one interval, *viz.* the octave, is kept absolutely correct and the remaining notes are sharpened or flattened, so that the major and minor tones are equalised, and each of them is made equal to two limmas or "semi-tones." There are thus twelve semi-tones in the octave, and if these be absolutely equal, any one of them may be taken as the key note, and all the scales so produced will be exactly similar. The following comparison shows the ratios of the frequencies of the notes in an equally tempered scale, the correct intervals being added for comparison:

C	D	E	F	G	A	B	C'
1	1·1250	1·2500	1·3333	1·5000	1·6666	1·8750	2
1	1·1224	1·2599	1·3348	1·4983	1·6818	1·8875	2

The scale of equal temperament is not exactly followed in practice, the result being that all keys are not quite the same, the errors being greater as the number of sharps or flats in the scale is increased, and also, in most cases, greater in sharp keys than in flat keys. The precise result depends to a large extent on the individual tuner of the instrument.

Perfectly just intonation may, of course, be obtained in music performed by the human voice, or by instruments of the violin class (*e.g.* a string quartet), so long as no instruments having fixed intervals are employed at the same time. The continued use of tempered scales has, however, largely impaired the sensitiveness of most musical ears to perfect intonation.

Tempera, Painting in. *See* PAINTING (METHODS).

Temperate Zones, North and South. The parts of the Earth's surface lying between the tropics and the Arctic or Antarctic Circle.

Temperature (*Heat*). Temperature is, in popular language, that which determines the hotness or coldness of a body. A hot body is said to have a high temperature, a cold body a low temperature, the terms "high" and "low" being merely relative, and varying within very wide limits according to the circumstances under which they are applied. A body, A, is at a *higher temperature* than a body, B, if, when they are placed in contact, heat flows from A to B. *See* MEASUREMENT OF TEMPERATURE.

——, **Absolute** (*Heat*). *See* ABSOLUTE TEMPERATURE.

——, **Critical** (*Heat*). *See* CRITICAL TEMPERATURE.

——, **Scales of** (*Heat*). *See* THERMOMETRIC SCALES.

Tempering (*Eng., etc.*) The process by which the hardness of steel tools, etc., is regulated according to the purpose for which they are intended. The tool is first hardened by heating to a temperature not exceeding that of a "cherry red," and then suddenly cooled by being plunged into cold water. The steel, if of proper quality, should now be so hard that it will scratch glass; it is however very brittle, and liable to fracture. If the steel be now cautiously heated, it is gradually rendered softer and less brittle; by stopping the heating at the proper moment, and again cooling by immersion in water, the tool may be left with the requisite "temper" for the purpose desired. To enable this to be judged, a portion of the tool is carefully brightened after hardening, so as to expose a clean surface of steel, free from scale or oxide. As the metal is heated, a succession of tints appear on the surface of the metal. These tints change as the temperature rises, and indicate with sufficient accuracy for practical purposes the exact moment when the heating must be stopped. The tints may be classified as in the following table, which also gives the approximate temperature attained, and the principal tools for which each temper is requisite:

	Temp. Fahr.	Tools.
Pale straw ...	430°	Surgical instruments, certain tools for cutting metal.
Darker straw ...	440° to 470°	Metal-working tools, razors, cold chisels, wood-working tools.
Brownish yellow	500°	Axes, plane irons, chipping chisels, and other tools which are subjected to shock or percussion.
Light purple ...	530°	Springs, swords.
Dark purple ...	570°	Saws.

Steel heated to higher temperatures than these becomes too soft for use in cutting tools. The purple tint gives way to a dark lilac, which gradually grows paler, assumes a greenish tint, and ultimately disappears.

In some cases the tempering is effected by covering the object with oil or grease, and heating it until the latter "flashes," or takes fire. This process is termed

Blazing or Blazing Off; it is often applied to saws and springs. In other cases, especially where a number of small objects have to be tempered at the same time, they are heated in a bath of oil, fusible metal, or alloy, to the required temperature. This method is largely used in tempering cutlery.

Tempering (*Pottery, etc.*) Thoroughly mixing clay and bringing it to a suitable condition of plasticity for moulding.

Template (*Build.*) The stone or wood block placed under the bearings of a beam or girder to support and distribute the pressure.

—— *or* **Templet** (*Eng., etc.*) A mould or pattern used to indicate the outline or form which has to be given to a piece of work. A template is usually cut from a thin sheet of wood or metal, the exact form being obtained by careful measurements taken from the working drawings.

Templating (*Eng., etc.*) The making of Templates (*q.v.*) In certain trades (*e.g.* boiler making) it is usual to entrust this operation to a special workman.

Temple (*Weaving*). A flat bar of wood fitted with small pins at each end or other device used in weaving to keep the cloth extended to its proper width to save the strain on the reed caused by the sucking in or shrinking of certain fabrics.

Templet. *See* Template.

Tempo (*Music*). Time, as *tempo di valse*, in the time of a valse; *tempo ordinario*, ordinary time, *i.e.* at a moderate speed.

Temporary Centre (*Eng.*) A piece of wood or metal is sometimes attached temporarily to an object for the purpose of carrying a centre mark which is required during subsequent operations; *e.g.* it may be necessary to find the exact centre of a hole. This must either be filled up or covered over by a piece of material on which the centre can be marked.

Temporary Hardness of Water. *See* Calcium Compounds, Clark's Process, *and* Water.

Temporary Mandrel (*Eng.*) A rod which is passed through a hole in an object such as a hollow tube or cylinder, in order that it may be supported between the centres of a lathe when the outside has to be turned.

Temporary Stars (*Astron.*) *See* Novæ.

Tenacity. *See* Tensile Strength.

Teneramente (*Music*). Tenderly.

Tenerezza, Con (*Music*) With tenderness; delicately.

Tenia (*Architect.*) *See* Tænia.

Tenon (*Carp. and Join.*) The ordinary form of tenon is shown in Fig. 1. A is the tenon proper, or

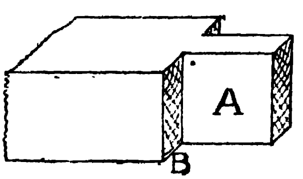


Fig. 1.

portion which fits into the mortice (*q.v.*): B is termed the shoulder of the tenon. Fig. 2 is a Haunched Tenon, the portion C, the Haunch or Haunching, being formed so as to fit into a ploughed groove such as that on the inner edge of the style of a door.

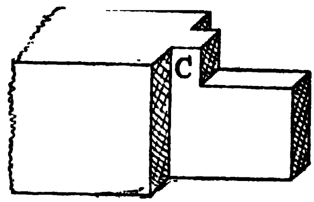

Fig. 2.

Fig. 3 shows a Double Tenon, and Fig. 4 is a Bareface Tenon, which has a shoulder formed on one side only. Fig. 5 shows a Tusk Tenon, used in

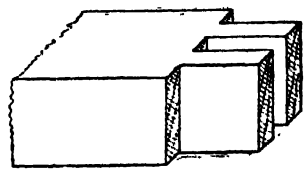

Fig. 3.

framing large structures such as floors. A is the tenon, B the shoulder, and the portion D is termed the Tusk. E is the joist into which the tenon is

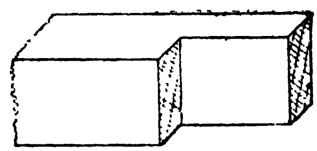

Fig. 4.

morticed, and F a key passing through the tenon. A tenon which does not pass right through the piece into which it is morticed is termed a Stub Tenon or

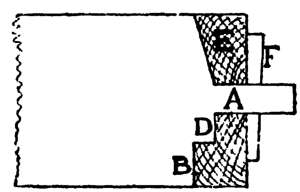

Fig. 5.

Stump Tenon. A Dovetail Tenon has one edge cut at an angle, like a dovetail, and it is held in position against a corresponding sloping side of its mortice by means of wedges. It may pass right through the material, or may form a stump tenon.

Tenoning Machine (*Carp., etc.*) A machine used in cutting tenons. It may consist of saws, two of which work parallel to each other (the distance between them being equal to the width of the tenon), and two more moving in a plane at right angles to the other two, for cutting out the shoulders of the tenon. More modern tenoning machines remove the material at the sides of the tenon by means of rotary cutters consisting of flat plane irons mounted in a revolving block.

Tenon Saw (*Carp. and Join.*) A saw with a parallel blade and an iron or brass back, used for cutting the shoulders of tenons, etc. *See* Saws.

Tenor (*Music*). (1) The highest of men's voices, with the exception of the alto. Generally speaking, the compass is an octave lower than the soprano. (2) The viola (*q.v.*) (3) The largest bell in a peal. A *tenore robusto* is a tenor singer with a full, strong voice. *See also* TENOR CLEF.

Tenor C (*Music*). The C an octave below middle C (*q.v.*)

Tenor Clef (*Music*). The C clef  on the fourth line. *See* STAVE *and* SCORE.

Tenorite (*Min.*) Black oxide of copper. Occurs as a non-crystalline mineral in the form of a powder, in masses, or as concretions. Forms an important copper ore in North America.

Tenor Trombone (*Music*). The trombone in B♭. *See* MUSICAL INSTRUMENTS, *p.* 437.

Tensile Strain (*Eng., etc.*) A strain consisting of an elongation produced in a piece of material by a pull or tensile stress.

Tensile Strength. The property of a material by virtue of which it resists forces tending to produce elongation. The term is sometimes applied to the ultimate stress which a given piece of material can withstand, or to the breaking load.

Tensile Stress (*Eng., etc.*) A force tending to elongate a body.

Tension of Vapour (*Heat*). *See* VAPOUR PRESSURE

Tension Rods, Bolts, etc. (*Eng.*) Rods or bolts which are used to resist tension. *See also* TIE.

Tenter (*Textile Manufac.*) A machine on which the cloth is stretched after scouring, milling, dyeing, etc. The common form of automatic tenter is horizontal, but it may also be vertical. The cloth passes on travelling tenter hooks over a series of steam pipes. In the blanket trade, in order not only to stretch the cloth, but to retain as much as possible of the natural handle of the wool and whiteness of colour, tentering is done in the open air on vertical frames.

Tenuto (*Music*). Abbreviation *ten.*, held. The term is used to signify that a certain note or chord is to be sustained for its full value. In modern songs, however, the term often signifies that a note is to be sustained for more than its proper length.

Terebene (*Chem.*) A mixture of inactive terpenes, boiling between 156° and 180°. It is a colourless liquid, insoluble in water, soluble in all organic solvents. It has an agreeable odour of pine-wood. Used in medicine in bronchitis and in coughs; it is either inhaled or taken on sugar. To prepare it, redistilled turpentine is shaken with sulphuric acid till its optical activity disappears; then the product is distilled in steam. Dipentene (*see* TERPENES) is an important constituent.

—— *and* **Terebenthene** (*Painting*). On account of the high price of turpentine many preparations have been made which are intended to replace this body, at all events on the market, although there is not one of them which is a really satisfactory substitute from the buyer's point of view. They go under various fancy names, more or less suggestive of turpentine, such as terebene, terebine, terebenthene, turpenteen, *cum multis aliis*. While some of them answer well enough for ordinary work, they all, as stated, fall short of true turpentine, especially in drying and in living power. They may be classed under three heads, those consisting simply of heavy petroleum oils, those consisting of mixtures of petroleum and rosin oils, and those consisting of mixtures of petroleum and rosin oils adulterated with real turpentine. As regards the proportions between the ingredients, each maker has his own recipe, and a good deal of the nomenclature depends upon this circumstance.

Terephthalic Acid (*Chem.*) 
White needles; sublimes on heating without melting; sparingly soluble in water, alcohol, ether, chloroform, and acetic acid. When heated with lime it forms benzene. It is obtained in a number of ways; thus it occurs as an oxidation product on boiling many terpenes with diluted nitric acid. It can be obtained by the diazo reaction (*q.v.*) from paramidobenzoic acid,

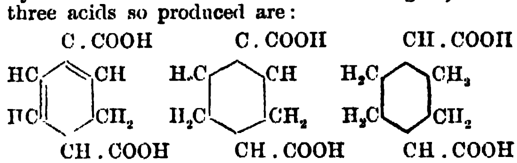
$$C_6H_4\begin{cases}COOH\\NH_2\end{cases} \rightarrow C_6H_4\begin{cases}COOH\\CN\end{cases} \rightarrow C_6H_4\begin{cases}COOH\\COOH\end{cases}$$

from paraxylene by heating it with bromine at 150° to form paraxylylene bromide, digesting the latter with alcohol potassium acetate, heating the acetate with alkaline permanganate, filtering and acidifying the product when the acid separates out:

$$C_6H_4\begin{cases}CH_3\\CH_3\end{cases} \rightarrow C_6H_4\begin{cases}CH_2Br\\CH_2Br\end{cases} \rightarrow$$

$$C_6H_4\begin{cases}CH_2.OOC.CH_3\\CH_2OOC.CH_3\end{cases} \rightarrow C_6H_4\begin{cases}COOH\\COOH\end{cases}$$

The reduction products of terephthalic acid have been carefully studied by Baeyer, who deduced the centric formula for benzene as a result of his work on these compounds. On reduction of the acid with sodium amalgam it adds two atoms of hydrogen in the cold, four atoms on heating, and six atoms with great difficulty (twenty hours' boiling of the tetrahydro acid with excess of sodium amalgam). The three acids so produced are:



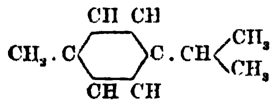
$\Delta^{1,5}$ dihydro-terephthalic acid. Δ^{1} tetrahydro-terephthalic acid. Hexahydro-terephthalic acid.

The $\Delta^{1,5}$ — and Δ^{1} — acids behave like true unsaturated compounds, adding bromine or hydrobromic acid directly, and reducing alkaline permanganate; but the hexahydro acid behaves like a saturated compound, and, although it reacts with bromine, it does so like a saturated fatty acid—that is, hydrogen is replaced by the halogen, and the hydrogen replaced is that attached to the carbon adjacent to the carboxyls. The hexahydro acid is known in two stereoisomeric forms. *See* STEREOISOMERISM. From the formula for terephthalic acid it will be seen that four dihydro acids are theoretically possible. All are known, and the $\Delta^{2,5}$ — acid occurs in two stereoisomeric forms. Two tetrahydro acids are possible, and both are known, the Δ^{2} — acid occurring in two stereoisomeric forms.

Terminal *or* **Terminus** (*Architect.*) An architectural feature, the lower part of which resembles an inverted truncated obelisk, while the upper part is frequently a bust of a man, woman, or satyr.

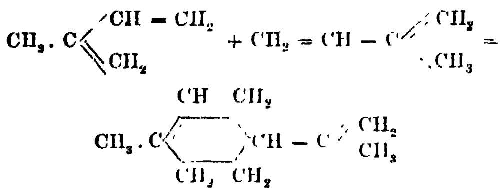
Terminator (*Astron.*) The line which separates the light from the dark portion of a sphere illuminated from one direction.

Terpenes (*Chem.*) Hydrocarbons of the formula $C_{10}H_{16}$. They are mostly ring compounds which may be regarded as related to paracymene,



but a few are open chain compounds of the olefine series. The terpenes and many of their derivatives occur in essential oils. Examples: Oil of bergamotte contains limonene and linalool (*q.v.*), also linalyl acetate; oil of camphor contains camphor (*q.v.*), pinene (*q.v.*), etc.; eucalyptus oil contains cineol and pinene; oil of geranium contains geraniol; oil of lavender contains pinene, limonene, linalyl acetate, geraniol, and cineol; oil of lemons contains citral and limonene; oil of peppermint contains menthol (*q.v.*) and its acetate; otto of roses contains geraniol and citronellol; oil of turpentine contains pinene. ***Except camphene, which is a solid, terpenes are liquids.*** They are volatile in steam; have an agreeable smell; most of them are optically active; some of them resinise on exposure to air and light. *See* PINENE. They polymerise when heated to about 300° to sesquiterpenes and polyterpenes. When caoutchouc is distilled it forms a hydrocarbon called isoprene C_5H_8 of the constitution $CH_2 = CH - C \begin{matrix} CH_2 \\ CH_3 \end{matrix}$

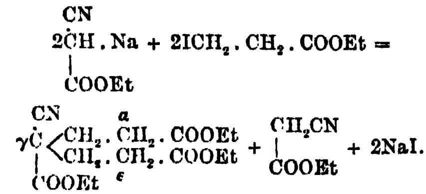
which easily polymerises to dipentene:



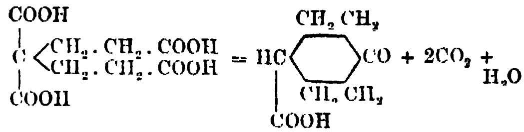
The compound isoprene is called a hemiterpene. Cadinene, an oil which boils at 275° and is found in oils of cade, patchouli, cubebs, galbanum, angostura, and many others, has the formula $C_{15}H_{24}$, and is called a sesquiterpene. So we have

Hemiterpene: Isoprene, C_5H_8.
Terpenes: about 13 of them $= 2 \times C_5H_8 = C_{10}H_{16}$.
Sesquiterpenes: few definitely known $= 3 \times C_5H_8 = C_{15}H_{24}$.
Polyterpenes: none exactly studied $= N \times C_5H_8 = (C_5H_8)_n$.

For the properties of a typical terpene, *see* PINENE. Another terpene of great interest and importance is *Limonene*, which contains an asymmetric carbon atom, and is known in its dextro, lævo, and racemic forms; the racemic form is called *Dipentene*. This terpene has recently been synthesised by Professor Perkin, and it is the first direct synthesis of a terpene which has ever been made. Ethyl β-iodopropionate and ethyl sodiumcyanacetate (from sodium ethoxide and ethyl cyanacetate) react at the ordinary temperature to form ethyl γ-cyanopentane-αγε-tricarboxylate,

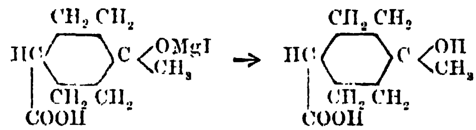


This ester is hydrolysed with hydrochloric acid, and the resulting acid heated with acetic anhydride:

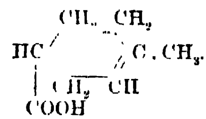


δ-ketohexahydrobenzoic acid.

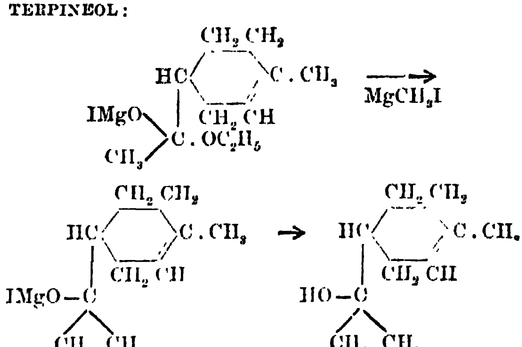
The ethyl ester of this acid yields on treatment with magnesium methyl iodide in ether, and hydrolysis of the product δ-hydroxyhexahydroparatoluic acid:



On solution of the lactone of this acid in fuming hydrobromic acid, the hydroxy group is replaced by bromine giving δ-bromhexahydroparatoluic acid, from which pyridine removes hydrogen bromide, giving Δ^3 – tetrahydroparatoluic acid:

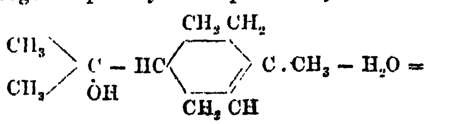


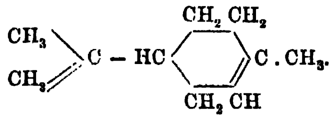
The ethyl ester of this acid with magnesium methyl iodide in ether yields an addition product which is decomposed by water with formation of inactive TERPINEOL:



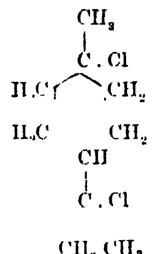
Terpineol.

Terpineol when heated for an hour with potassium hydrogen sulphate yields dipentene by loss of water:

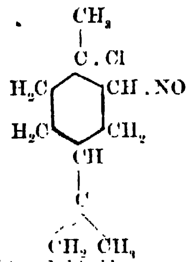




Dipentene is a colourless liquid; boils at 180°; has a smell of lemons; soluble in ether, alcohol, benzene, acetic acid; it occurs in a number of essential oils, *e.g.* cubebs, thyme, worm seed; and as it is formed from some other terpenes (camphene, pinene, and the limonenes at 250 to 300°) at a high temperature, it occurs in those turpentines which are distilled at a high temperature, namely, Russian and Swedish. It is formed by the union of equal quantities of *d*- and *l*-limonene, and from terpineol as described above; and along with other products from pinene by boiling with alcoholic sulphuric acid. To obtain pure dipentene its dihydrochloride is boiled with acetic acid and sodium acetate, the product distilled in steam, and the dipentene further purified by boiling with caustic potash, again distilling in steam, and fractionally distilling the dipentene. Dipentene adds four atoms of bromine directly to its molecule; it adds two molecules of hydrogen chloride, or hydrogen bromide. The dihydrobromide is known in two forms, *cis* and *trans*. Dipentene dihydrobromide is also formed by the addition of hydrogen bromide to limonene, cineol, and terpin. Dipentene also adds nitrosyl chloride molecule for molecule:

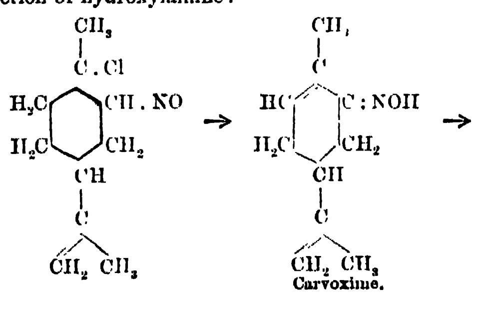


Dihydrochloride.

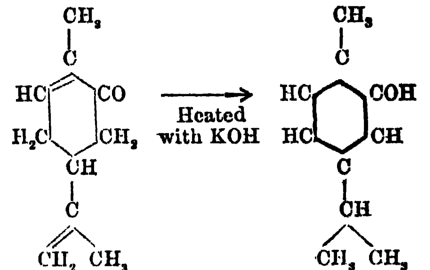


Nitrosyl chloride compound.

In the case of the **limonenes** hydrogen chloride is added in two stages, the first molecule being added on when dry hydrogen chloride is used, and the second when moist hydrogen chloride is used; as the first product is optically active, the addition must occur at the side chain. As regards the limonenes, the nitrosyl chloride compounds are active, and each limonene yields two stereoisomeric nitrosyl chlorides; since these are all active, addition must occur in the ring. When the nitrosyl chlorides are treated with alcoholic potash they yield the carvoximes $\{$d-, l-, and (d + l)$\}$ compounds, which are formed from carvone by the action of hydroxylamine:



Carvoxime.



Carvone. Carvacrol (*q.v.*)

As dipentene contains an asymmetric carbon atom, and is optically inactive, it should be composed of two oppositely active constituents; these constituents are the dextro and lævo limonenes. The limonenes occur in many essential oils (*see above*), and when mixed in equal quantities they yield dipentene. The remaining ring terpenes cannot be described here. Of the open chain, or olefinic terpenes, none has had its constitution settled beyond all doubt. As an example of this class of terpene *Myrcene* may be mentioned, which occurs in bay oil; as it passes into linalool (*q.v.*) by addition of the elements of water it has most probably the constitution

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>C:CH-CH_2-CH_2-\underset{CH_2}{C}-CH=CH_2 \quad \text{or}$$

$$\begin{matrix}CH_3\\CH_2\end{matrix}\!\!>C-CH_2-CH_2-CH_2-\underset{\underset{CH_2}{\|}}{C}-CH=CH_2$$

A few important derivatives of the terpenes are appended. *Citral*,

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>C:CH.CH_2.CH_2.\underset{CH_3}{C}:CH.CHO$$

is a colourless oily liquid, boils at 228° to 230°, and smells of lemons. Heated with acid potassium sulphate it yields paracymene; boiled with caustic it yields methyl heptenone,

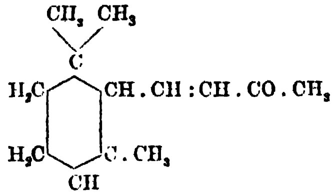
$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>C:CH.CH_2.CH_2.CO.CH_3;$$

reduced by sodium and alcohol it yields the corresponding alcohol geraniol. It unites with acid sodium sulphite. Citral is known in two stereoisomeric forms. With acetone in presence of alkali, citral condenses (shaken for several days with baryta water) to pseudo-ionone:

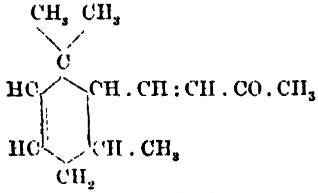
$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>C:CH.CH_2.CH_2.\underset{CH_3}{C}=CH.\underset{\underset{HC.CO.CH_3}{\|}}{CH}$$

This compound is known in two stereoisomeric forms. When pseudo-ionone is heated for some hours with dilute sulphuric acid and glycerine, it forms *Ionone*, which is a liquid boiling at 128° under a pressure of 12 mm. mercury, and in dilute alcoholic solution smells of violets and vine-blossom—hence it is largely used as a perfume.

Ionone is a mixture of two stereoisomers; its formula is—



The natural perfume of violets is due to a compound called *irone*, isomeric with ionone:



Citronellol, also called *Rhodinol*,

$$\begin{matrix} CH_3 \diagdown \\ CH_3 \diagup \end{matrix} C:CH.CH_2.CH_2.\underset{CH_3}{CH}.CH_2.CH_2OH$$

is one of the principal constituents of otto of roses; it is an oil smelling strongly of roses, boils at 117° under 17 mm. pressure, and is lævorotatory. The inactive form has recently been synthesised, so that its constitution is now quite certain: Sodium ethyl acetoacetate and ethylene dibromide give

$$\begin{matrix} CH_3 \\ | \\ CO \\ | \\ CH.CH_2.CH_2Br \\ | \\ COOEt \end{matrix}$$

which on saponification with caustic potash yields $CH_3CO.CH_2.CH_2.CH_2OH$. With hydriodic acid this alcohol gives its iodide, which is condensed with acetone and zinc to methyl heptenone,

$$CH_3.CO.CH_2.CH_2.CH_2I + Zn + CO(CH_3)_2 =$$
$$ZnIOH + CH_3.CO.CH_2.CH_2.CH:C \begin{matrix} CH_3 \\ CH_3 \end{matrix}$$

This ketone gives the ethyl ester of geranic acid when condensed with zinc and ethyl iodacetate

$$\begin{matrix} CH_3 \diagdown \\ CH_3 \end{matrix} C:CH.CH_2.\underset{OH}{C}:CH_2 + Zn + ICH_2.COOEt =$$

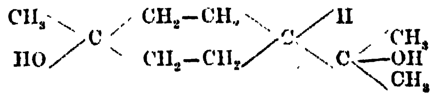
(Tautomeric form.)

$$ZnOHI + \begin{matrix} CH_3 \\ CH_3 \end{matrix} \rangle C:CH.CH_2\ CH_2.C.CH_3$$
$$\qquad\qquad\qquad\qquad\qquad \underset{}{CH.COOEt}$$

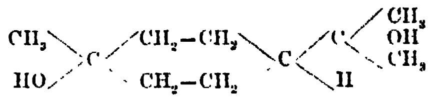
This ester reduced by sodium and alcohol to the ethyl ester of citronellic acid, then to inactive rhodinol. It is used in perfumery; thus an artificial otto of roses is made (patented) as follows: 80 parts geraniol, 10 parts rhodinol, 1 part phenylethyl alcohol, 2 parts linalool, 0·25 parts citral, and 0·5 parts octyl aldehyde. *Geraniol*,

$$\begin{matrix} CH_3 \diagdown \\ CH_3 \end{matrix} \rangle C:CH.CH_2.CH_2.\underset{CH_3}{C}:CH.CH_2OH$$

occurs in oil of geranium and in otto of roses; it is an oil which smells of roses and geraniums; boils at 229°, and is optically inactive. It is the alcohol corresponding to citral, which it yields on careful oxidation; it unites with calcium chloride; heated with water at 200° it is in part rearranged to linalool (*q.v.*); dilute sulphuric acid converts it to terpineol. *Terpin* is a dihydric alcohol, and is known in the cis- and trans-forms (*see* STEREOISOMERISM):

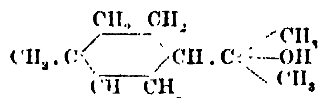


Cis-form M.P. 104°.

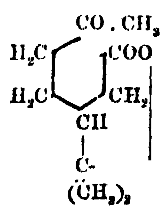


Trans-form M.P. 264°.

They are both white crystalline solids obtained from the corresponding cis- and trans- limonenedihydrobromides by converting them into acetates by means of silver acetate and saponifying the esters with alcoholic potash. They can be reconverted by shaking with hydrobromic acid. Dehydrating agents readily convert them into dipentene. The cis-terpin readily takes up a molecular proportion of water forming *Terpin hydrate*, which is a well crystallising solid; melts at 120° when rapidly heated, giving off steam, and passing into terpin again. The halogen acids give the cis- and trans-dipentenedihalogen acid addition products. Boiled with dilute acids it yields terpineol and other products. It is formed from turpentine by the action of dilute nitric acid and alcohol, from the dihydrochlorides of dipentene and d-limonene by the action of water, and from linalool (*q.v.*), geraniol, and terpineol by the action of dilute acids. *Terpineol*,



is a white crystalline solid which melts at 35°, but shows to a remarkable degree the property known as superfusion, so that it is commonly met with as a liquid; boils at 215° to 218° (134°—135° at 60 mm.); it has a pleasant smell of lilac. It forms a nitrosochloride; also a phenylurethane with phenyl isocyanate, which melts at 113°. $CO\begin{matrix} \diagup NHC_6H_5 \\ \diagdown OC_{10}H_{17} \end{matrix}$ When shaken during three days with benzene and 5 per cent. sulphuric acid, it passes into terpin hydrate. Distilled with acid potassium sulphate (*see above*) it gives dipentene. On oxidation with chromic acid it yields a ketolactone of the formula—



which on further oxidation with potassium permanganate yields acetic and terpenylic acids—

$CH_3 . COOH$ and 
Terpineol has been synthesised (*see above*). It is obtained by allowing French turpentine to stand for twelve hours with ·5 parts concentrated sulphuric acid and 1·5 parts of 90 per cent. alcohol; or by heating terpin hydrate with 1 per cent. sulphuric acid, then crystallising and purifying by fractional distillation. Terpineol is largely used as a perfume, alone as in scenting soap, or mixed with other perfumes.

Terra Alba (*Dec.*) This is powdered gypsum (*q.v.*) The mineral is prepared merely by grinding. It answers better as a water colour than with oil, as it has more body with water than with the latter vehicle. It is a very pure white, except when tinged yellow by iron. It can, however, be purified from iron by treatment with dilute hydrochloric acid. It is absolutely permanent to light and air and chemical action, being as permanent as barytes itself. In spite of its cheapness, its want of body (*q.v.*) is a great bar to its use. Paper makers and stainers are probably the largest users of it. In use with paper, body is not of very great importance, and gypsum combines the advantages of permanence, cheapness, and miscibility with all other pigments. Moreover, its cheapness secures it from adulteration, but it would be even cheaper were not large quantities of gypsum used for the manufacture of plaster of Paris. This substance can also be used as an oil paint (it sets hard with water), but is inferior to the unburnt gypsum.

Terracotta. A hard pottery, generally unglazed, composed of fine clay, fine grained sand, crushed pottery, or other similar materials. The colour varies with the materials used, but terracotta is sometimes specially coloured. Used as a building material and for small works of art, *e.g.* statuettes. *Cf.* TANAGRA FIGURINES.

Terra di Sienna (*Paint.*) A ferruginous earth of a fine yellow colour, used as a pigment in oil and water colour painting. It is known respectively as raw or burnt sienna (*q.v.*)

Terra Nera (*Paint*). An unctuous black pigment used by ancient artists in tempera, fresco, and oil painting.

Terrestrial Equator (*Astron.*) *See* EQUATOR, TERRESTRIAL.

Terrestrial Magnetism (*Elect.*) The phenomena arising from the magnetic properties of the earth. *See* DIP, DECLINATION, MAGNETIC ELEMENTS, *etc.*

Terrestrial Radiation (*Meteorol.*) The escape of heat from the earth's surface into the atmosphere.

Terre Verte, Terra Verde (*Paint.*) Genuine terre verte is essentially a silicate of iron and magnesia, found native in many places. It occurs in the Mendip Hills, and two other important localities are Cyprus and Verona, whence the name Verona Earth. The pigment requires no preparation beyond grinding. It varies much in hue according to the locality from which it was obtained, but there is always a bluish grey tinge about it. It is absolutely permanent in air, and, curiously enough, resists sulphurous fumes perfectly, in spite of the fact that it contains iron. It can be mixed with any other pigment and can be used either as a water or as an oil colour. It has very little body, and occupies an intermediate place between the body colours and the glazing colours. Copper greens are sometimes fraudulently sold as terre verte, but this is at once detected if the substance is exposed to the action of sulphuretted hydrogen, which has no effect on genuine terre verte, but blackens copper greens. Dilute acids again have little action on terre verte, but dissolve copper greens, forming a solution which is turned blue by ammonia.

Tertiary (*Geol.*) The TERTIARY ROCKS embrace those strata newer than the SECONDARIES (*i.e.* the Chalk), but older than the most recent formations, *e.g.* the Glacial deposits. *See* STRATA, TABLE OF (*in Appendix*).

Tertiary Alcohols (*Chem.*) Alcohols of the formula $\begin{matrix}R_1\\R_2\\R_3\end{matrix}\!\!>\!C.OH$, where R_1, R_2, R_3 are monovalent hydrocarbon residues which may be the same or different. Examples:

$$\begin{matrix}CH_3\\CH_3\\CH_3\end{matrix}\!\!>\!C.OH \qquad \begin{matrix}CH_3\\CH_3\\C_2H_5\end{matrix}\!\!>\!C.OH$$

Trimethyl carbinol. Dimethylethyl carbinol.

They are liquids with a smell resembling that of camphor; they lose water somewhat readily on heating, forming olefines, *e.g.* $(CH_3)_3COH$ gives $(CH_3)_2C:CH_2$. On oxidation they yield acids containing a smaller number of carbon atoms than the original alcohol; thus trimethylcarbinol yields acetic acid, but also acetone and a little isobutyric acid $(CH_3)_2CH.COOH$. Their nitro-derivatives are distinguished from those of primary and secondary alcohols by being unacted upon by nitrous acid. They are obtained by the action of zinc alkyls on acid chlorides; or by absorbing suitable olefines in sulphuric acid and distilling the product with water; *e.g.*:

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!CH.CH_2OH \xrightarrow[\text{with } H_2SO_4]{\text{Heated}} \begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!C:CH_2 \text{ with } H_2SO_4$$

Isobutyl alcohol.

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!CHSO_4.CH_3 \xrightarrow[H_2O]{} \begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!C\!<\!\begin{matrix}OH\\CH_3\end{matrix}$$

Tertiary Amines (*Chem.*) Compounds in which an atom of nitrogen is united to three hydrocarbon radicals. Example: Trimethylamine (*q.v.*)

Tertiary Bases (*Chem.*) Compounds of the formula $\begin{matrix}R_1\\R_2\\R_3\end{matrix}\!\!>\!N$ or $\begin{matrix}=C\\-C-\end{matrix}\!\!>\!N$ where R_1, R_2, R_3 are radicals united to the nitrogen atom by carbon and $\begin{matrix}=C\\-C\end{matrix}\!\!>\!N$ is part of a ring. Examples:

Trimethylamine $\begin{matrix}CH_3\\CH_3\\CH_3\end{matrix}\!\!>\!N$

Pyridine 
All tertiary bases add alkyl iodides, directly forming quaternary ammonium iodides, *eg.* $N(CH_4)_4I$.

Tertiary Colours (*Paint.*) *See* COLOURS, TERTIARY.

Tertiary Hydrocarbons (*Chem.*) Hydrocarbons which contain one or more carbon atoms united to four other carbon atoms—*eg.* Hexamethylmethane.

$$\begin{array}{ccccccc} & & CH_3 & & CH_3 & & \\ & & | & & | & & \\ CH_3 & - & C & — & C & - & CH_3 \\ & & | & & | & & \\ & & CH_3 & & CH_3 & & \end{array}$$

See also PARAFFINS.

Tesla Coil (*Elect.*) A name applied to an induction coil for producing currents of very high potential and frequency. The primary coil consists of a few turns of thick wire, without any iron core; through this coil pass the rapidly oscillating currents produced by the discharge across an air-gap of a Leyden jar or other condenser, which is itself charged by means of an induction coil of the ordinary type, or by a transformer which is wound so as to give a secondary current of very high voltage. An oscillatory discharge (*q.v.*) occurs through the primary of the Tesla coil, and this induces a secondary current of exceedingly high voltage and frequency in the secondary winding, which consists usually of one layer of fine wire, wound on an insulating cylindrical support. In some cases both coils are immersed in a bath of oil, the apparatus being then often termed an OIL COIL; but in most modern forms air insulation is found to be sufficient.

Tesselated Pavement (*Dec.*) A floor formed of small coloured tiles laid in geometrical patterns. *Cf.* MOSAIC.

Test (*Chem., Phys., etc.*) (1) An experimental operation undertaken to ascertain the nature, condition, strength, or other properties of a given substance, apparatus, structure, etc. (2) A reagent or substance used in making such a test.

—— (*Eng.*) An operation carried out in order to ascertain the strength, quality, or other properties of some material, structure, or machine.

—— (*Zool.*) The hard external or rigid parts of an organism.

Testa (*Botany*). The term applied to the coat of a seed. When an inner seed coat is present it is termed the endopleura or tegmen. The testa may become hard and woody, as in the so-called Brazil nut. The "husk" of the sunflower and similar "seeds" is the fruit wall, not the testa.

Test Bars (*Eng.*) Bars of metal, etc., suitably shaped for testing in a testing machine or otherwise. Test bars are often made of the same material as that employed in the execution of an order, so that the quality of the material used can be accurately determined; the conditions to be satisfied are frequently laid down in the specification.

Test Cocks (*Eng.*) Small cocks in a steam boiler, one being fixed above, the other below, the water line, in order to indicate the level of the water inside.

Testing Machine (*Eng.*) A machine by means of which a known stress of large amount can be applied to a suitable piece of material, in order to measure its elastic constants or its breaking strength. The form of testing machine most commonly met with is one by which a tensile or compressive stress is applied to a rod or bar. One end of the bar is firmly gripped by strong jaws attached to the ram of a hydraulic press: the other end is similarly connected to the shorter arm of a lever. The longer arm of this lever carries a weight which can be moved along the arm till the pull exerted on the bar is counterbalanced and the lever brought into a position of equilibrium. The lever is graduated after the manner of a steelyard, so that by observing the position of the weight at any instant the amount of the force acting on the bar can be read off. The extension produced in the bar is measured by various methods—a reading microscope or cathetometer, a purely mechanical device, or some combination of optical and mechanical apparatus, such as the Extensometer of Ewing. Recording apparatus is sometimes constructed so as to trace automatically a curve on paper showing the relation of the stress and strain in the bar throughout the experiment. Testing machines are also constructed for applying and measuring transverse, torsional, or compressive stresses.

Testing of Drains. *See under* SANITATION.

Test Specimens (*Eng.*) *See* TEST BARS.

Tetartohedrism (*Min.*) The possession by a crystal of only one-fourth of the number of faces which are required by the symmetry of the system to which the crystal belongs. *See also* SYSTEMS OF CRYSTALS.

Tetrachord (*Music*). A series of four sounds; the half division of modern scales. *See* SCALE *and* TEMPERAMENT.

Tetradymite (*Min.*) A mineral allied to BISMUTHINE (*q.v.*) It is a sulphide of lead, but contains in addition some tellurium.

Tetragonal (*Min.*) *See* SYSTEMS OF CRYSTALS.

Tetrahedrite *or* **Fahlerz** (*Min.*) A sulphide of copper and antimony, with other metals; copper 38·6, sulphur 26·3, antimony 16·5, arsenic 7·2, with iron, zinc, and silver. The latter mineral may be present in considerable quantity (*e.g* 30 per cent.), and the mineral is then termed SILVER FAHLERZ or ARGENTIFEROUS GREY COPPER ORE. Cubic System, also massive. Colour grey to black. Cornwall, Devon, Scotland, Central Europe, N. America. It is an important ore of Copper, and also of Silver.

Tetrahedron. A pyramid having a triangular base.

Tetrastyle (*Architect.*) A term applied to a temple which has four columns in the front row. *See* DISTYLE, DECASTYLE, HEXASTYLE, OCTASTYLE.

Tetratomic Molecules (*Chem.*) A term applied to elements having molecules composed of four atoms. Such elements are phosphorus and arsenic at a temperature of about 1,000°. *See also* MOLECULE.

Tetravalent Element *or* **Group** (*Chem.*) *See* VALENCY.

Tetronal (*Chem.*) (Propione diethyl sulphone, *or* diethyl sulphone diethylmethane.) A white crystalline solid; melts at 85°. It is prepared and acts like sulphonal (*q.v.*)

Th (*Chem.*) The symbol for Thorium (*q.v.*)

Thalassic Deposits (*Geol.*) *See* DEEP SEA DEPOSITS.

Thallium (*Chem.*), Tl. Atomic weight, 204. A rather rare white metal; melts at 294°; boils about 1500°. Its vapour density at 1725° shows it to have a diatomic molecule, but the lowering of the vapour pressure in mercury solution points to its having a monatomic molecule when in solution in mercury. Its specific gravity is near that of lead, being 11·9.

In air it is easily oxidised to the monoxide Tl_2O. It dissolves readily in sulphuric and nitric acids, dilute or strong: less readily in hydrochloric acid owing to the low solubility of its chloride (0·265 in 100 at 16°) in water. On solution in these acids it forms thallous salts. The metal was discovered, and is readily detected, by its flame spectrum—a single bright green line. Thallium occurs in small amount in some kinds of iron and copper pyrites, in a Swedish mineral called crookesite, and in a number of mineral springs. One method of obtaining thallium is to boil the flue dust from pyrites which contains thallium, with water, and precipitate the clear solution with common salt; the crude thallous chloride so precipitated is washed with common salt solution; transformed into sulphate and again precipitated with common salt—this removes arsenic; about 30 to 50 grams of pure chloride are obtained from 3,000 grams of dust. The chloride is converted into the acid sulphate by heating with sulphuric acid, dissolved in water, and the solution electrolysed, using a platinum anode and a copper cathode: the metal separates in large shining leaves and needles; it is quickly washed and may be melted under potassium cyanide. The position of this element in the Periodic System (Group III., Series 11) scarcely gives a correct idea of its chemical relationships. The thallous salts have formulæ corresponding to those of the alkali metals (K : Na). The oxide Tl_2O, which is black, dissolves in water forming a hydroxide TlOH, which is also soluble in water, with strong alkaline reaction and the property of absorbing carbon dioxide to form the soluble carbonate Tl_2CO_3. The chloride TlCl crystallises in cubes like common salt, but is sparingly soluble in water like lead chloride; yet, like potassium chloride, it forms an extremely sparingly soluble platinum double chloride, Tl_2PtCl_6. The bromide (pale yellow) and the iodide (bright yellow) are much less soluble than the chloride. The sulphate is isomorphous with potassium sulphate, but less soluble in water, and it forms sulphates of the type $Tl_2SO_4MSO_46H_2O$ where M = Fe, Mg, or Ni, and also alums; its sulphide is black, insoluble in water, but soluble in acids. Like aluminium, which occurs in the same group, it forms an oxide, thallic oxide, Tl_2O_3, which is obtained by burning the metal in oxygen; but it is a brownish black solid, and quite unlike aluminium in that it behaves as a pretty typical peroxide. Derived from this oxide are a few unstable salts of the same type as the aluminium salts, but far more readily hydrolysed by water, and the thallic sulphate $Tl_2(SO_4)_3$ does not appear to form alums.

Thallophyta (*Botany*). A subdivision of the Plant kingdom comprising the plants lower than mosses and liverworts—namely, the Algæ and Fungi. They are characterised by having a simple plant body or thallus.

Thallus (*Botany*). A term applied to the simple plant body of the Algæ and Fungi. Usually there is but little separation into root, stem, and leaf. A thallus may be filamentous or membranous, unicellular or multicellular.

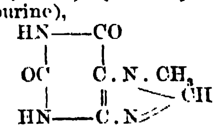
Thebaine (*Chem.*) $C_{19}H_{21}NO_3$. An alkaloid occurring to the extent of about 0·15 per cent. in opium. It is a white crystalline solid; melts at 193°; nearly insoluble in water, soluble in alcohol; lævorotatory. Its constitution is not settled, but it is a tertiary base. It contains two methoxy groups and a reduced phenanthrene ring. It produces convulsions when administered to animals.

Theine (*Chem.*) Another name for CAFFEINE (*q.v.*)

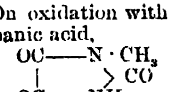
Theme (*Music*). The principal subject of a musical composition.

Thenard's Blue (*Dec.*) This is a cobalt pigment containing alumina. Thenard originally prepared it from Swedish cobalt ore, but it is now usually made by precipitating mixed solution of a cobalt salt (usually the nitrate or the sulphate) and alum with carbonate of soda. The filtrate is filtered off, washed, dried, and ignited at a red heat. It is hardly possible to use too high a temperature, and the fiercer the heat the greater will be the resistance of the pigment to external influences. Cobaltous sulphate, ignited when mixed dry with ammonia alum, also gives Thenard's blue, but prolonged ignition is necessary. In all cases the alum must be free from iron, a very common impurity, or the purity of the blue will be spoiled by the presence of brownish red sesqui-oxide of iron. Various other processes have been employed for making this blue. Binder precipitated hydrate of alumina with potash and chloride of cobalt with ammonia in separate vessels and mixed the precipitates in suspension in water after they had been thoroughly washed and dried, and ignited the mixture. The shade of the pigment varies with the proportions of the two metals present. A rough average is probably 80 per cent. of alumina and 15 per cent. of cobaltous oxide. According to Bouillai Marillai, a very rich and velvety blue is obtained by substituting phosphate of lime for alumina. The phosphate of lime and cobalt oxide are precipitated separately according to Binder's principle, and then mixed. An equally good result can, however, be obtained by making a paste of freshly precipitated alumina with a strong solution of cobalt chloride, drying the paste, and then grinding the dry mass to a fine powder, and heating it to a white heat for an hour. This last process entirely obviates the red tint which is often the great drawback of Thenard's blue. It must be remembered that whenever Thenard's blue is made by ignition it must be completely shielded from the combustion gases by heating it in crucibles with tightly luted lids. If the pigment has been exposed to the gases its colour is always dull and uncertain. Thenard's blue is quite unchanged by exposure to air and light, and few chemicals have any action upon it. It can be used either as an oil or as a water colour, and can be mixed with any other pigment whatsoever.

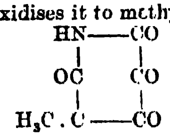
Theobromine (*Chem.*) (Dimethylxanthine, 3 : 7-dimethyl-6-oxy-purine),



A micro-crystalline solid; sublimes without decomposition when carefully heated at 290° to 295°; slightly soluble in water; only sparingly soluble in alcohol, ether, chloroform. Behaves both as a feeble base and acid. On oxidation with chromic acid it gives methylparabanic acid,



Chlorine water oxidises it to methyl alloxan,



It yields a crystalline silver salt when its boiling ammonia solution is precipitated with silver nitrate, and this silver salt when heated with methyl iodide gives caffeine (*q.v.*) The physiological action of theobromine is similar to but stronger than that of caffeine. It occurs to the extent of ½ to 2 per cent. in cocoa beans, and is prepared from them by finely powdering, extracting by boiling water, precipitating with lead acetate, and freeing the clear filtrate from excess of lead by sulphuretted hydrogen. On evaporating the clear filtrate to dryness and extracting with boiling alcohol a solution is obtained which deposits theobromine on cooling. Theobromine is used to a small extent in medicine, and the salicylate of its sodium salt is also used under the name Diuretin. Theobromine is synthesised from xanthine (*q.v.*) by heating its lead salt with methyl iodide at 100°. *See also* PURINES.

Theodolite (*Surveying*). The principal instrument used in surveying. It consists essentially of a small telescope, mounted on a suitable stand, and capable of rotation about both its horizontal and vertical axes. It is fitted with graduated scales for the accurate determination of the amount of angular movement in either plane, and with screws for the levelling of the instrument. *See* SURVEYING.

Theorem of Three Moments (*Eng.*) *See* THREE MOMENTS, THEOREM OF.

Thermal Conductivity (*Heat*). This is defined as follows: Let there be a plate of any material of area A and uniform thickness d; let the sides be maintained at temperatures t_1 and t_2, and let H units of heat pass through the plate in T seconds. Then if k be the thermal conductivity of the material,

$$H = k\frac{A(t_1 - t_2)T}{d}$$

From this equation it appears that the thermal conductivity is the quantity of heat which passes in unit time through unit area of a plate of unit thickness, when unit difference of temperature is maintained between its two sides.

Thermal Efficiency of an Engine (*Heat*). *See* PERFECT ENGINE.

Thermal Unit (*Heat*). The unit in which heat is measured is the quantity of heat necessary to raise unit mass of water, through unit rise of temperature. The unit of mass is usually the pound or gram, the unit rise of temperature is 1° Fahrenheit or 1° Centigrade. This definition is sufficiently exact for most purposes, but the actual value varies with the initial temperature. This fact may be otherwise expressed by saying that the Specific Heat of water is not quite constant. *See also* CALORIE.

Thermal Value. The amount of heat obtained by the complete combustion of a given quantity of some fuel.

Thermite (*Chem.*) The mixture of aluminium powder and ferric oxide used in Goldschmidt's process (*q.v.*)

Thermo-Chemistry. That branch of chemistry which deals with the measurement of the heat evolved or absorbed in reactions, and which applies the results of such measurements to the solution of various chemical problems, such as the determination of constitution, etc. The measurements of heat can be made either in terms of the units of heat or work, *viz.*:

The small calorie = the heat required to raise one gram of water through 1° C. at 18° C.—denoted by cal.

The large calorie = 1000 small calories—denoted by Cal.

The erg = $2{\cdot}391 \times 10^{-8}$ cal.

The joule = 10^7 ergs = 0·2391 cal.—denoted by j.

The kilojoule = 1000 j = 239·1 cal.—denoted by Kj.

[1 cal = $4{\cdot}183 \times 10^7$ ergs = J.]

The quantities of substances used in the experiments may be any that are convenient, but the results should be referred to the gram molecule. Thus when hydrogen burns in chlorine to form hydrogen chloride, the heat evolved in the formation of 36·5 grams of hydrogen chloride is now the usual way of expressing the result: it is equal to 22,000 cal, or 92 Kj. In practice, only reactions which proceed quickly can be investigated, such as those between acids and bases, combustions, and the like. The apparatus employed for reaction of the first kind may be an ordinary calorimeter; for reactions of the second kind a "bomb" apparatus devised by Berthelot and Vieille is used; it consists of a strong steel vessel coated inside with platinum and provided with a rod which supports a platinum dish (in which a known weight of the substance is placed), and also serves as a support for one end of a small iron spiral of known weight, the other end of which is supported by a second rod; both rods are attached to wires which pass to the outside. The vessel is provided also with a screw valve, so that compressed oxygen can be introduced (25 atmospheres or more). A vessel containing a known quantity of water surrounds the combustion chamber, the temperature of the water being registered by a thermometer which will allow at least $\frac{1}{500}$ of a degree to be read; surrounding the water chamber is a vessel containing dry air, and highly polished inside. Solids or non-volatile liquids may be placed directly in the platinum dish; volatile liquids are put in collodion balloons; substances which cannot be ignited in this way are mixed with a known weight of a substance such as naphthalene. When the current is passed, the iron spiral is fused and ignited, and the drops of burning iron ignite the substance. The water equivalent of the bomb must be known, and of course the heat of combustion of the iron spiral and any added substance must be deducted from the result. When the heat evolved in a reaction cannot be measured directly, or when it is desired to obtain the heat of formation (*q.v.*) of a compound which is not formed by the direct union of its elements, indirect methods are employed. These indirect methods are based on what is known as the Law of Constant Heat Summation (see this for an example given in full). An enormous amount of thermochemical data has been accumulated, but little use is made of it in pure chemistry. In applied science the thermo-chemistry of fuel is of great importance; in physiology the heat value of food is of some importance, for practically all the heat of the body is due to chemical changes occurring in it. A few examples of results in pure chemistry are appended:

$$\begin{aligned}(1)\quad 2Al + 3O &= Al_2O_3 + 754 \text{ Cal.}\\ C + O_2 &= CO_2 + 93{\cdot}6 \text{ Cal.}\\ 4Na + O_2 &= 2Na_2O + 2 \times 100 \text{ Cal.}\\ 4Fe + 3O_2 &= 2Fe_2O_3 + 2 \times 19{\cdot}5 \text{ Cal.}\end{aligned}$$

Hence it may be inferred that aluminium oxide will not be reduced to the metal by heating it with carbon or with sodium, but that if aluminium were heated with ferric oxide or with sodium oxide it would be capable of reducing them to the metal. The Goldschmidt process (*q.v.*) is an application of a knowledge

of the high heat of formation of aluminium oxide to a useful purpose.

(2) $H_2 + I_2 = 2HI - 2 \times 60{\cdot}5$ Cal.
$H_2 + I_2 + aq = 2HI\ aq + 2 \times 13$ Cal.

Thus it will be seen that hydrogen iodide is formed from hydrogen and solid iodine, with considerable absorption of heat. When the gas is dissolved in water, heat is evolved until the solution attains a specific gravity of 1·56 (about 50 per cent. HI), after which no more heat is evolved, although a solution of sp. gr. 1·7 (about 58 per cent.) can be obtained. It has been suggested that the reducing action of concentrated hydriodic acid is due to this 8 per cent. or so of the endothermic hydrogen iodide, which evolves no heat on solution.

(3) The heats of formation of the halogen compounds of the elements are periodic functions of the atomic weights of the elements.

(4) In organic chemistry there is a fairly constant increase in the heat of formation for an increment of CH_2 in homologous series. Heats of neutralisation of isomeric bases are occasionally of use in determining constitution; thus the heat of neutralisation with hydrochloric acid for

Aniline is . . .	74 Kj.
o-chloraniline is .	63 „
m-chloraniline is .	66 „
p-chloraniline is .	72 „

Stohmann has attempted to show that in the benzene ring there are not three equal valued double bindings by comparing the increase in the heat of combustion on addition of hydrogen to the ring in the case of benzene and phthalic and terephthalic acids. An example is:

Benzene to dihydrobenzene	+68·2 Cal.
Dihydrobenzene to tetrahydrobenzene .	+44·0 Cal.
Tetrahydrobenzene to hexahydrobenzene	+41·2 Cal.
Hexahydrobenzene to hexane . . .	+58·0 Cal.
Phthalic acid to dihydro acid . . .	+68·7 Cal.
Dihydro acid to tetrahydro acid . . .	+45·3 Cal.
Tetrahydro acid to hexahydro acid . .	+45·3 Cal.
Hexahydro acid to suberic acid . . .	+54·8 Cal.

It will be seen that a much larger amount of heat is evolved on adding the first two hydrogen atoms than in all subsequent additions, even on splitting of the ring; but it must be added that no such difference occurs in other physical properties on addition of the first two hydrogen atoms to benzene, as, for instance, density, and molecular refraction.—W. H. H.

Thermodynamics (*Heat*). The investigation of the relations between heat and other forms of energy. These relations are governed by two fundamental laws. *See* THERMODYNAMICS, LAWS OF.

Thermodynamics, Laws of (*Heat*). The FIRST LAW states that if a quantity of heat be entirely converted into mechanical energy, the amount of such energy is a fixed quantity; and, *vice versa*, a given quantity of mechanical energy is convertible into a given fixed quantity of heat. In other words, the ratio of the quantity of heat to the quantity of mechanical energy is constant. This is algebraically expressed by the equation $W = J H$, in which J represents the Mechanical Equivalent of Heat (*q.v.*) The SECOND LAW cannot be so simply expressed. Lord Kelvin's statement of this law is as follows: "It is impossible, by means of inanimate material agency, to derive mechanical effect from any portion of matter by cooling it below the temperature of the coldest of surrounding bodies." Clausius' mode of expressing the law is: "It is impossible for a self-acting machine, unaided by any external agency, to convey heat from one body to another at a higher temperature."

Thermo-Electricity. It was discovered by Seebeck (in 1821) that if a circuit be formed by joining two dissimilar metal conductors together at their ends, and one junction be heated, a current will flow in the circuit. For example, let an iron wire and a copper wire be twisted together at their ends, and one junction be heated, a current will flow from the copper to the iron at the hot junction; we have what is termed a THERMO-ELECTRIC CURRENT, and the pair of metals form a THERMO-ELECTRIC COUPLE. For the sake of comparison, the E.M.F. produced by a couple made of each of the following metals respectively, with lead as the second metal, is given. The temperature difference between the hot and cold junctions is in each 1° C:

Bismuth . .	about	90	microvolts.
Nickel . .	„	22	„
German Silver .	„	12	„

This electromotive force is termed the THERMO-ELECTRIC POWER of the metal. The E.M.F. of a couple depends upon the temperatures of the junctions in a manner which may be expressed by the formula

$$E = a(T_2 - T_1) + b(T_2^2 - T_1^2),$$

where E is the E.M.F., T_2 and T_1 the temperatures of the junctions, and a and b coefficients depending on the metals employed. If the *mean* temperature of the two junctions attain a certain value, the E.M.F. vanishes: this temperature is termed the NEUTRAL TEMPERATURE, and is given by the equation

$$\frac{T_2 + T_1}{2} = -\frac{a}{2b} = T_n$$

From this equation it is easily seen that

$$a = -2b\,T_n$$

and from the first formula

$$E = 2b(T_2 - T_1)\left(\frac{T_2 + T_1}{2} - T_n\right)$$

Thus E vanishes when $T_2 = T_1$, and also if $\frac{1}{2}(T_2 + T_1) = T_n$. If one junction be kept at a constant temperature, the E.M.F. attains a maximum when the other is at the neutral point; while, if one be kept at the neutral point, the E.M.F. will gradually fall in amount as the other is heated, vanishing when the two junctions are at the same temperature, and becoming reversed if the second junction is heated above the neutral point. This phenomenon is termed THERMO-ELECTRIC INVERSION.

A thermo-electric couple supplies a very convenient method of measuring high temperature; for this purpose the wires are often platinum and a platinum-iridium alloy. The couple is connected in series with a high resistance galvanometer, the scale of which may be graduated to read directly in degrees. A number of couples are frequently connected in series in such a manner that the alternate junctions may be simultaneously exposed to a source of heat. Such an arrangement constitutes a THERMO-ELECTRIC PILE or THERMOPILE, and is commonly employed for the detection and measurement of radiant energy. In the RADIO-MICROMETER of Boys a single couple, forming part of a closed circuit, is suspended by a

delicate quartz fibre between the poles of a powerful magnet, such as is used in suspended coil galvanometers. Radiant energy falling on the junction produces an E.M.F., which sets up a current in the suspended circuit, which then acts in the same way as the coil of a galvanometer. This instrument is so delicate that it has enabled the radiant heat from a candle two miles away to be detected.

PELTIER EFFECT: Peltier found (1834) that a reversible thermal effect occurs when a current flows across a junction of two dissimilar metals, heat being liberated when the current flows in one direction, and absorbed when it flows in the other. The amount of heat liberated or absorbed in a given time is proportional to the current, and is perfectly distinct from the "Joule Effect" or production of heat, which depends upon the resistance of the conductor.

THOMSON EFFECT: Lord Kelvin (Sir William Thomson) found that if different parts of any given conductor in which a current is flowing are at different temperatures, there is, in general, an absorption or a liberation of heat. Heat is absorbed in an iron conductor if a current flow from a hot to a cold point; in copper the reverse is the case. If there be a small difference of temperature, $t_1—t_2$, between two adjacent points in the conductor, the heat developed in the part between these two points, when unit quantity of electricity flows from one to the other, is $\sigma\ (t_1—t_2)$. The coefficient σ is called the "Specific Heat of the electricity in the metal."

Thermo - Electric Power, etc. (*Elect.*) *See* THERMO-ELECTRICITY.

Thermometer (*Heat*). An instrument for the MEASUREMENT OF TEMPERATURE (*q.v.*)

——, **Electric** (*Heat*). *See* MEASUREMENT OF TEMPERATURE.

——, **Maximum and Minimum** (*Heat*). *See* MAXIMUM AND MINIMUM THERMOMETER.

——, **Mercurial** (*Heat*). *See* MEASUREMENT OF TEMPERATURE.

——, **Platinum** (*Heat*). *See* MEASUREMENT OF TEMPERATURE.

—— **Resistance** (*Heat*). *See* MEASUREMENT OF TEMPERATURE.

Thermometer Screen (*Meteorol.*) A box or case, perforated in order to allow the free circulation of air, used to protect a thermometer from the direct action of the sun's rays. The thermometer gives the true temperature of the air. The commonest pattern is Stevenson's Screen, with sides made of parallel shutters or louvers.

Thermometric Conductivity, Coefficient of (*Heat*). The diffusivity of a substance. *See* DIFFUSIVITY.

Thermometric Scales (*Heat*). *See* SCALE, THERMOMETRIC.

Thermopile (*Elect.*) *See* THERMO-ELECTRICITY.

Thermostat. An instrument for regulating temperature or for maintaining a uniform temperature.

Thicknessing (*Carp.*) Planing down wood to a required thickness. The operation is effected in large shops by a planing machine, which is furnished with two cutter blocks, the distance between which can be adjusted; the machine is termed a Thicknessing Machine.

Thicknessing Machine (*Carp., etc.*) *See* THICKNESSING.

Thick Spaces (*Typog.*) Spaces used for dividing words and cast three to an em of their own body. *See* TYPES.

Thimble (*Eng.*) A term often used for a cylindrical or conical socket; also for a conical mandrel used in forging rings, which are slid on in order to preserve the circular form while being hammered.

—— (*Plumb.*) A brass socket for attaching lead pipes to stoneware.

—— (*Pot.*) The smallest size of flower pot made, being 2 in. deep and 2 in. in diameter. The next size ($2\frac{1}{2}$ in. by $2\frac{1}{2}$ in.) is called "Thumbs."

Thin Fount (*Typog.*) Founts of type of which the lower case letters *a* to *z* measure in width less than twelve times the depth of their body are called thin founts.

Thinners (*Dec.*) Linseed oil and turpentine form the usual thinners of the house painter, these liquids being employed to thin the finely ground pigments to a consistency suitable for being applied to a surface by means of a brush. The oil serves to bind the particles of the pigment together, and the turpentine serves to further "thin" the mixture or render it more liquid. *See* LINSEED OIL *and* TURPENTINE. Although the thinners used by house painters almost universally are confined to linseed oil and turpentine, in no fixed proportions, it is recognised by the best authorities that they may be varied with advantage according to the nature of the pigment. Thus, when oxide of zinc (*q.v.*) or zinc white is employed, it is important to use very little turpentine with the addition of only refined boiled linseed oil. Some paint manufacturers who prepare special paints send them out in paste form with liquid thinners of exactly the proper composition ready to be added as the paint is mixed. This practice has much to recommend it, and is likely to increase.

Thinning Out *or* **Down** (*Eng.*) Bevelling the edges of boiler plates, etc., where they are to overlap at a joint.

Thin Plates and Films, Colours of (*Light*). When light falls on a thin plate of any transparent material, interference occurs between the light which is reflected at the front surface and that which is reflected at the back surface. In the case of a plate of uniform thickness the interference may be complete for light of one particular wave length; if this was the wave length of the incident light, then the interference will be a maximum, and the amount of light reflected will vanish. If the incident light was white, then one colour will be destroyed, and the resultant light will become coloured. If the thickness of the film varies, the colours which are destroyed will also vary, and different tints will be produced in the reflected light. NEWTON'S RINGS form a good example of these colours. A lens of small curvature is laid on a glass plate, and successive rings appear surrounding a central spot, which is dark when viewed by transmitted light. With mono-chromatic light the surrounding rings are alternately bright and dark; with white light they appear coloured. If the rings be viewed by transmitted light, the central spot is bright, and the positions of the bright and dark rings are interchanged, a bright one occurring where a dark one appeared by the reflected light, and *vice versa*.

Thin Spaces (*Typog.*) Spaces used for dividing words and cast five to an em of their own body. *See* TYPES.

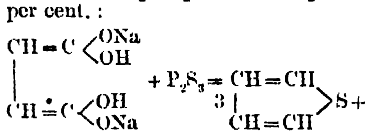
Thio- (*Chem.*) A prefix used in naming sulphur compounds. In most cases it indicates that in the compound bearing the prefix one or more sulphur atoms have replaced one or more oxygen atoms.

Carbonic acid	H_2CO_3	Thiocarbonic acid	H_2CS_3
Cyanic acid	HCNO	Thiocyanic acid	HCNS
Sulphuric acid	H_2SO_4	Thiosulphuric acid	$H_2S_2O_3$
Urea	$CO(NH_2)_2$	Thiourea	$CS(NH_2)_2$

Thiocyanates (*Chem.*) Another name for SULPHOCYANATES (*q.v.*)

Thionine (*Chem.*) Another name for LAUTH'S VIOLET (*q.v.*)

Thiophene (*Chem.*) 
A colourless liquid; boils at 84°; insoluble in water, soluble in benzene, ether, etc.; has faint smell resembling benzene. It is attacked by halogens more readily than benzene, even iodine forming substitution products with it in presence of mercuric oxide; the halogens first enter the α-position. Strong nitric acid oxidises thiophene, but if air charged with thiophene vapour is led into nitric acid, nitro compounds (mono- and di-) are formed. Forms a sulphonic acid when a dilute solution in light petroleum is shaken with concentrated sulphuric acid. Thiophene and its derivatives on treatment with a little isatin and some concentrated sulphuric acid give a deep blue colour—this is called the Indophenine reaction. Thiophene can be obtained by heating sodium succinate with phosphorus trisulphide—yield about 50 per cent.:



(Tautomeric form.)

It was first obtained from coal tar benzene, in which it occurs to the extent of about ½ per cent.; the benzene is shaken with concentrated sulphuric acid, the acid is diluted with water and distilled in steam, when nearly pure thiophene is obtained—the product is separated from water, dried, and redistilled. Thiophene is obtained in small quantity by passing acetylene through boiling sulphur.

Homologues of thiophene occur in coal tar; thus α-methylthiophene occurs in coal tar toluene. They can be obtained synthetically from diketones and γ-ketonic acids. Examples: (1) Phosphorus pentasulphide converts acetonyl acetone (*see* DIKETONES) into $\alpha\alpha'$-dimethylthiophene. (2) Phosphorus pentasulphide converts lævulinic acid into methylthiophene. *See* LÆVULINIC ACID. The homologues can also be obtained from the halogen substitution products of thiophene just as benzene homologues are obtained from benzene. On oxidation the homologues of thiophene yield thiophene carboxylic acids just as homologues of benzene yield benzene carboxylic acids.

Thiosulphates (*Chem.*) Salts of thiosulphuric acid $H_2S_2O_3$. This acid may be regarded as derived from sulphuric acid by replacement of an atom of oxygen by an atom of sulphur. The constitution of sulphuric acid is $\begin{smallmatrix}O\\O\end{smallmatrix}\!>S<\!\begin{smallmatrix}OH\\OH\end{smallmatrix}$ Thiosulphuric is regarded as derived from it by replacement of one of the hydroxyl oxygen atoms by a sulphur atom $\begin{smallmatrix}O\\O\end{smallmatrix}\!>S<\!\begin{smallmatrix}OH\\SH\end{smallmatrix}$ That it is a hydroxyl oxygen that is replaced is shown by several reactions of formation and decomposition of the thiosulphates, *e.g.*:

(1) A thiosulphate is formed when iodine acts on a normal sulphite in presence of a normal sulphide—

$$O_2S<\begin{smallmatrix}ONa\\Na\end{smallmatrix} + Na_2S + I_2 = O_2S<\begin{smallmatrix}ONa\\SNa\end{smallmatrix} + 2NaI.$$

$$O_2S<\begin{smallmatrix}ONa\\Na\end{smallmatrix} + C_2H_5SNa + I_2 = O_2S<\begin{smallmatrix}ONa\\SC_2H_5\end{smallmatrix} + 2NaI.$$

(2) When sodium ethyl thiosulphate is decomposed by a dilute acid mercaptan and sodium acid sulphate are formed—

$$O_2S<\begin{smallmatrix}ONa\\SC_2H_5\end{smallmatrix} + HOH = O_2S<\begin{smallmatrix}ONa\\OH\end{smallmatrix} + HSC_2H_5.$$

(3) Gentle warming of silver thiosulphate with water gives silver sulphide and sulphuric acid—

$$O_2S<\begin{smallmatrix}OAg\\SAg\end{smallmatrix} + HOH = O_2S<\begin{smallmatrix}OH\\OH\end{smallmatrix} + SAg_2$$

If the constitution of thiosulphuric acid is $O_2S<\begin{smallmatrix}OH\\SH\end{smallmatrix}$ isomerism should exist among the thiosulphates, and this is the case—

I. $O_2S<\begin{smallmatrix}ONa\\SK\end{smallmatrix}$	II. $O_2S<\begin{smallmatrix}OK\\SNa\end{smallmatrix}$
Melts at 62°.	Melts at 57°.
105·3 parts dissolve in 100 parts water at 15°; with ethyl bromide it gives $O_2S<\begin{smallmatrix}ONa\\SC_2H_5\end{smallmatrix}$	213·7 parts dissolve in 100 parts water at 15°; with ethyl bromide it gives $O_2S<\begin{smallmatrix}OK\\SC_2H_5\end{smallmatrix}$

Salt I. is prepared by neutralising sodium hydrogen sulphite with potassium carbonate, and acting on the product with ammonium pentasulphide; salt II. in a similar way from potassium hydrogen sulphite.

Third (*Music*). The interval between two notes occupying two degrees of the stave next but one to each other, as E, G. *See* INTERVALS *and* TEMPERAMENT.

Third Flute (*Music*). The flute in E♭. *See* MUSICAL INSTRUMENTS, *p.* 434.

Thistle (*Her.*) The flower and leaves of one of the *Carduus* family form the Emblem of Scotland. A very ancient order of knighthood is entitled the Most Noble and Ancient Order of the Thistle of Scotland.

Tholos (*Architect.*) Originally used to denote the roof of a circular building, but the term came to be applied to the circular building. *See* PELASGIC.

Thomson Effect (*Elect.*) If a current flow along a conductor whose temperature varies at different points, heat is absorbed at a given point, or is liberated at the same point, according to the direction of the current. In an unequally heated iron wire, heat is absorbed when the current flows from the hotter to the colder part of the wire; while with copper heat is absorbed when the current flows from the colder to the hotter part of the wire. A reversal of the current reverses the thermal effect in all cases. This effect is quite distinct from the heating effect which occurs in accordance with Joule's law (*q.v.*)

Thorax (*Zoology*). The anterior part of the trunk of an animal. It is protected by the ribs at the sides and by the sternum (breastbone) on the under (ventral) surface.

Thorium (*Chem.*) Th. Atomic weight 232·5. A rare metal belonging to Group IV. Series 12 in the Periodic System. It is a white metal; sp. gr. 11; it has not been melted; burns brightly when heated in oxygen; dissolves in nitric acid and aqua regia. Thorium occurs as silicate in thorite and orangeite, and as phosphate in monazite; it also occurs in a number of other minerals, but those mentioned are the chief source of the metal and its compounds. The metal is obtained by heating potassium thorium chloride $KCl.2ThCl_4$, with sodium under a layer of common salt in an iron cylinder with screw cover. There is some doubt as to whether thorium and its compounds are radioactive; according to some chemists, thorium prepared from uranium-free minerals is inactive. However, ordinary thorium and its compounds—for example, a Welsbach gas mantle—are radioactive: they give out the α, β, and γ rays (*see* RADIOACTIVITY), but the energy radiated as α-rays is about 22 times as much as that radiated by the β-rays, and it has been calculated that 1 gram of thorium emits about 70,000 α-particles per second, which is equivalent to 0·3 gram calories per year. Thorium and its compounds also yield an emanation which can be removed from them by merely drawing a current of air over the selected compound (usually the oxide); the emanation accompanies the air current; it is a gas which condenses between $-120°$ and $-155°$, and is unacted on chemically by any physical or chemical treatment, such as strongly heating it, treating it with acids and the like, but it decomposes spontaneously. The amount of the emanation is excessively small; there is present at any one time in 1 gram of thorium which is in a state of radioactive equilibrium not more than 5×10^{-14}cc. at the ordinary temperature and pressure. The thorium atom (or if not thorium some other unknown element which usually accompanies thorium), therefore, is unstable and decomposes; the stages of the decomposition so far as they are known may be represented thus:

Thorium

ThoriumX * — α-particle

Emanation† (a gas) — α-particle (1 or more)

EmanationX ‡ (a solid) — α-particle

Inactive substance

Active substance

α-particle — β-particle — ?

γ-rays

ThoriumX (ThX) can be obtained from thorium nitrate by precipitating the hydroxide with ammonia (*not* by caustic soda), filtering and evaporating the solution in a platinum dish—it is of course not visible or weighable. As thorium is undergoing decomposition, it is of interest to know how long a given mass would take to decompose completely: to give some idea of this, it has been calculated that of a given mass of thorium only 1 per cent. would remain at the end of 10^{10} years. COMPOUNDS: The oxide ThO_2 is the starting point for the preparation of the metal and its compounds. It is obtained, for instance, from thorite by evaporating it in finely powdered condition with hydrochloric acid, extracting the heated residue with water, removing lead by sulphuretted hydrogen, and precipitating the filtrate from the lead sulphide with ammonia. The very impure hydroxide is washed, dissolved in hydrochloric acid, and precipitated by oxalic acid. After washing, the oxalate is heated to convert it to oxide. The oxide, which still contains traces of other metals, is moistened with water, and heated with concentrated sulphuric acid in a platinum dish, when it forms the sulphate, which is dried, powdered, and dissolved in the minimum of water at 0°: on allowing the temperature to rise to 20°, the hydrate $Th(SO_4)_2 9H_2O$ separates out—this depends on the fact that the hydrate $Th(SO_4)_2 9H_2O$ is less soluble than any other hydrate up to 43°, and that its solubility increases rather rapidly above 20°. The process is repeated till a pure salt is obtained. Its solution is then precipitated by ammonia, and the hydroxide strongly heated to convert it into oxide. The oxide is a white powder which has not been melted. After it has been strongly heated, it is insoluble in acids except strong sulphuric acid. It is used in the preparation of the Welsbach mantle, and for this purpose it is prepared by heating the nitrate. *See* FLAME. The hydroxide $Th(OH)_4$ is obtained by precipitating any soluble thorium salt with ammonia: it is soluble in acids forming the corresponding salts. The chloride $ThCl_4$ is a white crystalline solid, somewhat deliquescent; crystallises from water with $8H_2O$; has a normal vapour density at 1050°. It is obtained by heating the metal in dry hydrogen chloride, or by heating a mixture of the oxide and carbon in a current of chlorine. The nitrate $Th(NO_3)_4$ is very soluble in water, and is obtained by dissolving the freshly precipitated hydroxide in nitric acid: it gives the oxide when heated. The sulphate $Th(SO_4)_2$ is obtained as described above, and is remarkable for the number of its hydrates and their stability. The hydrate $Th(SO_4)_2 9H_2O$ is the least soluble up to 43°, at which temperature it decomposes into $Th(SO_4)_2 4H_2O$, which diminishes in solubility from 18° to 100°, when it decomposes into $Th(SO_4)_2 2H_2O$. Over 45° the hydrate $Th(SO_4)_2 4H_2O$ is the least soluble. The carbide ThC_2 is a transparent crystalline solid, obtained by heating the oxide with sugar charcoal in the electric furnace: it is decomposed by water giving a number of hydrocarbons, among which are acetylene (47 per cent.), methane (29 per cent.), ethylene (6 per cent.), and, in addition to these, about 18 per cent. of hydrogen.

Thorne Composing Machines. *See* TYPE SETTING MACHINES.

Thorough Bass (*Music*). The continuous bass, bearing figures to show what harmony is to accompany it, in a composition. The term is often used

* Loses half its activity in four days. † Loses half its activity in one minute.
‡ Loses half its activity in eleven hours; cause of excited radioactivity; soluble in hydrochloric and sulphuric acids (the emanation is not soluble in these acids).

to denote any figured bass, whether *basso continuo* or not. Also as a term synonymous with harmony, as "the rules of thorough bass," meaning "the rules of harmony"; this, however, is not the real meaning of the term. For example of figured bass, *see* SCORE.

Thread (*Eng.*) *See* SCREW.

Thread Gait (*Lace Manufac.*) The available space between any two carriages in a lace machine.

Threading (*Lace Manufac.*) The operation of placing the brass bobbin properly into its carriage or shuttle, and threading the end of the material through the hole or guide.

Three Coat Work (*Plastering*). Plastering executed in three successive coats, viz. (1) Pricking-up Coat, (2) Floating Coat, (3) Setting Coat.

Three Colour Process. *See* PHOTO ENGRAVING *and* PHOTOGRAPHY IN COLOURS.

Three High Rolls *or* **Mill** (*Eng.*) A rolling mill with three rollers one above another. *Cf.* TWO HIGH.

Three Moments, Theorem of (*Mech. Eng.*) A theorem by which the bending moment at the points of support may be determined in the case of a "continuous" beam or girder, *i.e.* one resting on three (or more) supports. For a detailed discussion of this theorem, works on the Theory of Structures, etc., must be consulted.

Three Part Box (*Foundry*). A moulding box or flask in three separate parts; used in cases where a casting has to be made with a central portion which does not allow the easy withdrawal of the pattern.

Three Phase System (*Elect. Eng.*) A system of generating and distributing electric energy, which is of great value when power has to be transmitted over a considerable distance. An alternate current generator is used, which produces three alternating currents, differing in phase by one-third of a complete period, *i.e.* by 120°. It is only necessary to use three wires for the distribution of the three currents; the use of these three wires must, however, be carefully distinguished from that of the conductors in a three wire system (*q.v.*)

Three Quarter (*Bind.*) A book cover the back of which is of leather, extra wide, the corners covered with leather, and the sides with cloth or paper.

—— (*Paint.*) The term denotes a size of portraiture 30 in. long by 25 in. wide, the figure being shown to the hips. *Cf.* KIT-CAT.

Three Quarter Bat (*Build.*) Three-fourths of a brick used in the place of a closer and a header in a brick wall.

Three Square (*Eng.*) Three sided, or triangular in section.

Three Throw Crank (*Eng.*) Three cranks carried on one shaft, the angle between two consecutive cranks being 120°.

Three Throw Pump (*Eng.*) A pump with three barrels, the plungers or pistons being driven by a three throw crank (*q.v.*)

Three Wire System (*Elect. Eng.*) A system of electrical distribution, in which two dynamos are employed, and are connected to three distributing conductors. One of these, the NEUTRAL or BALANCING WIRE, is connected to the positive brush of one dynamo and the negative brush of the other; the remaining wires are connected to the two other brushes respectively. The lamps, etc., supplied by the system are connected to the neutral wire and one of the other wires, and so arranged that approximately equal numbers are connected to each of the two "outer" or principal conductors. The current in the neutral wire is then equal to the difference of the currents in the two other wires, and may be zero.

Threshold (*Build.*) The stone step of a doorway.

Thrice-marked Octave (*Music*). *See* PITCH.

Throat (*Eng., etc.*) (1) The opening at the top of a blast furnace. (2) A part of an object corresponding to the opening or neck of a bottle.

Throating (*Build.*) The groove cut on the underside of a skylight, transome of a frame, stone cills, etc. This groove serves to prevent the rain from running along the under surface by capillary attraction, and finding an entrance through crevices, especially in the case of skylights.

Throstle Frame (*Cotton Spinning, etc.*) A system of flyer spinning which is fast falling into disuse. It is being superseded by the ring frame (*q.v.*)

Throttle Valve (*Eng.*) A valve placed in the pipe which supplies steam (or gas) to an engine; the supply is controlled by opening or closing the throttle valve, which operation is effected in steam engines by the governor (*q.v.*)

Throttling (*Eng.*) Regulating the supply of steam (or gas, etc., in the case of a gas engine) by means of a throttle valve.

Through Stone (*Masonry*). A bonding stone going through the thickness of a wall.

Throw (*Eng.*) (1) An old term for a LATHE (*q.v.*) (2) The diameter of the circle described by the centre of a crank pin; it equals the stroke of the piston.

Throw of a Fault (*Geol.*) The amount of the vertical displacement produced in strata by a fault (*q.v.*)

Throw Off Impression (*Print.*) An arrangement by which the cylinder of a printing machine is raised clear of the forme, which may then travel beneath without an impression being made.

Thrust (*Eng.*) A pressure, particularly that exerted along the axis of a rod or a shaft.

Thrust Block *or* **Bearing** (*Eng.*) The bearing which takes the longitudinal thrust in a propeller shaft; it contains a number of grooves, in which corresponding rings or collars (the THRUST COLLARS) formed on the shaft rotate. The thrust is thus received directly by surfaces of metal, which are normal, or at right angles, to the force which they have to overcome, hence lateral motion of the shaft is prevented.

Thrust Collars (*Eng.*) *See* THRUST BLOCK.

Thrust Plane (*Geol.*) The plane of dislocation in a reversed fault (*q.v.*) Also termed a GLIDING PLANE.

Thrust Screw (*Eng.*) A screw placed in line with a rotating shaft or mandrel, with its end in contact with the end of the shaft: its use is to take any thrust in the shaft, and to provide a longitudinal adjustment for the latter. Used in some forms of drilling machine, lathe, etc.

Thuja occidentalis (*Botany*). A tincture used in pharmacy, made from the young shoots of the *Arbor vitæ* (*Coniferæ*).

Thumb (*Pot.*) *See* THIMBLE.

Thumb Lever Composing Stick (*Typog.*) So called because the slide is fixed by pressing down a lever.

Thumb Mould (*Join.*) A moulding used on the edge of tables.

Thumb Plane (*Join.*) Small planes, 3 or 4 in. long, used in working mouldings, rebates, etc., in situations where an ordinary plane cannot be used conveniently.

Thumb Screw (*Eng.*) A small screw with a head so formed that it can be turned by the thumb and finger.

Thumb Screw Composing Stick (*Typog.*) So called when the slide is fixed by means of a thumb screw. *See* COMPOSING STICK.

Thumper (*Music*). The level felted weight against which organ keys hit when they rise. Its duty is to keep the key level.

Thunder (*Meteorol.*) The noise corresponding to that produced by the passage of an electric spark. It is due to the sudden heating and consequent expansion and contraction of the air column. The rumbling noise is caused by numerous refractions and reflections from adjacent clouds and hills.

Thunderstorm (*Meteorol.*) Local progressive atmospheric disturbances occurring in most latitudes; accompanied by rain and electrical phenomena such as lightning.

Thurible. A CENSER (*q.v.*)

Thus (Frankincense *or* Olibanum). A resin which gives out a marked odour on being burnt, and is one of the main constituents of the mixture called incense, burnt in religious ceremonies. The name "incense" refers to the combustion which develops the odour. Thus is the dried exudation of certain resinous trees, and comes from Africa and Arabia. It has been known from very remote antiquity, and has been used for chewing as well as for fumigating. The name Olibanum is derived from the Hebrew word for milk (lebonah), and refers to the milky appearance of the sap before it hardens on exposure to the air. The Arabian and East African product is obtained from various species of *Boswellia*, while the West African olibanum, which comes mostly from Sierra Leone, is a product of *Daniellia thurifera*. Frankincense occurs in commerce in the form of pear-shaped "tears," always covered with a white dust. When this is rubbed off, the masses are seen to be either milky or clear and semi-transparent. The colour is a pale yellowish red, very faint in the best qualities. As regards constitution, it is a gum resin, containing about 33 per cent. of a gum said to be identical with gum arabic, and 56 per cent. of a resin which is separated from the gum by alcohol, in which the latter is insoluble. The remaining 9 per cent. or thereabouts consists of an essential oil easily obtained by distilling the frankincense with water or in a current of steam. This oil is sometimes quite colourless, but is usually somewhat yellow, and has the same smell as the burning incense, which therefore probably owes its odour to the volatilisation of unburnt oil. It is a matter of common knowledge that incense is burnt in partially closed vessels, not only for the convenience for swinging, but to restrict the access of atmospheric oxygen. The oil has a specific gravity of about 0·88, and is lævorotatory. It consists mainly of terpenes, and therefore boils at about 170° C., but its constitution is not accurately known. The oil was formerly largely used in medicine, and is still so to some extent, although it is not officinal. Frankincense and its oil are very similar to myrrh and the essential oil obtained from that resin. *See also* GUM THUS.

Thymol (*Botany*). An antiseptic substance obtained from the volatile oils of the plants *Thymus vulgaris*, *Monarda punctata*, *Carum copticum* (order, *Labiatæ*).

—— (*Chem.*)

$$CH_3.C\begin{matrix}\diagup CH-CH \diagdown \\ \diagdown CH-COH \diagup\end{matrix}C.CH(CH_3)_2$$ (3-methyl-6-isopropylphenol).

A colourless solid crystallising in large tables; melts at 44°; boils at 230°; slightly soluble in water (1 in 1500); soluble in alcohol and ether. It has a smell of thyme. It dissolves in caustic soda or potash, forming crystalline salts, which liberate thymol on treating them with an acid. Distillation with phosphorus pentasulphide converts it into cymene (*q.v.*) On oxidation with chromic acid it yields a quinone. When acted on by iodine in alkaline solution it yields a monoiodo derivative, a diodo derivative, or a diododiphenyl derivative according to the conditions of the experiment. The last of these substances contains 46 per cent. of iodine, and is used as an antiseptic under the name aristol; the only advantage it has over iodoform is that it has very little odour. Thymol occurs in oil of thyme, which may contain as much as 30 per cent. of it; it is obtained from this oil by shaking with caustic soda, separating the soda solution, and precipitating it with hydrochloric acid; the precipitate is crystallised from acetic acid. Thymol is a stronger antiseptic than phenol and is used in medicine as an antiseptic; its slight solubility in water is perhaps against its general use.

Thyrsus (*Archæol.*, *Art*). An attribute of Dionysus (Bacchus) and his votaries. It consists generally of a staff tipped with an ornament like a pine cone, sometimes wreathed with ivy or vine branches, but various forms are recorded.

Tiara. (1) A headdress somewhat like a turban, worn by the ancient Persians. The tiara is still the ceremonial headdress of the kings of Persia. (2) The Pope's triple crown, a tapering cylindrical diadem surrounded by three crowns, and surmounted by a mound and cross. (3) A coronet and ornament for the head in the form of a coronet.

Tibia (*Archæol.*) A variety of flagolet or flute, made either single or double.

—— (*Zool.*) In a mammal one of the two bones forming that portion of the leg (hind limb) lying between the knee and the foot. The term is also applied to a part of one of the appendages in certain invertebrates.

Tidal Basin (*Civil Eng.*) A dock which communicates through lock gates with tidal water. Vessels can enter as soon as the tide reaches the level of the water in the basin. *See* DOCKS.

Tides (*Astron.*) Alterations which occur in the depth of a large body of water, owing to the attraction exerted by the sun and moon. Water drawn from one place (where it is low tide) is accumulated at another (where it is high tide). This phenomenon is progressive, the tides following the relative motions of the earth, moon, and sun. The theory of the tides is long and complex. It is given in full in works on Gravitational Astronomy. *See* PRIMING OF THE TIDES.

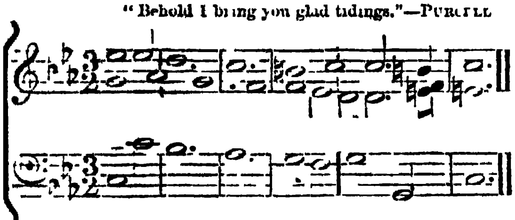
Tie (*Eng.*) A member of a structure which exerts a tensile force between two other parts. It is usually a thin rod, which is theoretically capable of being replaced by a chain or cord.

—— (*Music*). *See* BIND. To what is stated there may be added the following: Mr. Franklin Taylor points out that occasionally in pianoforte music the second note is actually repeated in such a way that the note is rapidly and closely restruck before the damper has quite fallen, so that there is no actual silence between the two sounds. The following is an example:

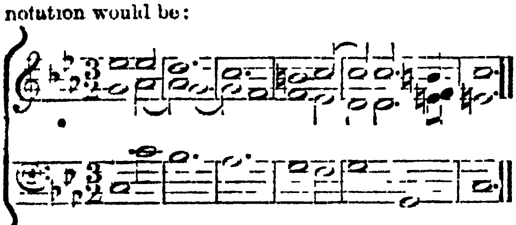
Valse Op. 34, No. 1.—CHOPIN.

In older music ties were less used, the notes being written as follows:

"Behold I bring you glad tidings."—PURCELL.



In modern music ties are invariably used when a note is sustained in two bars. The above in modern notation would be:



—— (*Silk Manufac.*) The term applied to an arrangement of threads in plain weaving, *e.g.* "satin" tie, "twill" tie, etc.

Tie Beam. *See* ROOFS.

Tie Bolt (*Eng.*) A bolt serving as a tie (*q.v.*)

Tier, Teir, *or* **Rangs** (*Lace Manufac.*) A row of carriages in working position.

Tierce (*Music*). A metal organ stop sounding the third in the second octave, *i.e.* the seventeenth, of the foundation stop. It is seldom found in modern organs, owing to the difficulties in introducing it under the equal temperament tuning. The tierce now forms one of the ranks in the mixtures (*q.v.*)

Tierce de Picardie (*Music*). The third in a major chord which closes a piece written in the minor key. The older composers always used this chord in minor key compositions for the final chord, or else omitted the third altogether. An example is given from Purcell's anthem *under* TIE.

Tiercerons (*Architect.*) *See* RIB AND PANEL VAULT.

Tie Rod (*Eng.*) *See* TIE.

Tiger Nut (*Botany*). The tuberous rhizomes of *Cyperus esculentus* (order, *Cyperaceæ*), rich in starch and oil, are used as an article of food in Southern Europe, where they are known under the various names of "Chufa," "Amande de terre," "Souchet comestible." They are exported from the Gold Coast under the name of tiger nuts.

Tightening Pulley (*Eng.*) A pulley used for tightening or taking up the slack in a belt, driving cord, or chain. The pulley can be moved and clamped in any position within certain limits.

Tile (*Build.*) (1) Generally a thin piece of baked clay finished according to the purposes for which it is intended, *e.g.* covering roofs, floors, walls, or for lining furnaces. Tiles are also made of porcelain, glass, marble, metal, etc. Roofing tiles are made in various forms, but the most usual form is the pantile (*q.v.*) Tiles are also made for use in specific parts of a roof, *e.g.* crest tiles, ridge tiles, etc. (2) The name given to a short earthenware pipe used in making a drain.

Tile Ore (*Min.*) A red or reddish brown variety of CUPRITE (*q.v.*) containing a certain percentage of iron.

Till (*Geol.*) A name given in Scotland to BOULDER CLAY—*i.e.* a glacial material enclosing boulders and angular fragments of numerous older rocks.

Tilt, Tilting. Charging with the lance or spear.

Tilt Hammer (*Met.*) An early form of power hammer. It may be compared to a large hand hammer, pivoted at one end of its handle, and gradually raised by a cam or projection on a wheel revolving immediately underneath the shaft. When the cam passed a certain point, the hammer fell suddenly, striking a heavy blow. It was much used in puddling mills and forges, but is now obsolete.

Tilting Fillet (*Carp. and Join.*) *See* SPROCKET PIECES.

Tilting Helmet (*Arm.*) A heavy helmet used in the fifteenth and sixteenth centuries at the joust or tilt (*q.v.*) The lumière or opening for vision was high up so that the wearer could only see his opponent when bending forward in the saddle for the course. *Cf.* TOURNEY HELMET.

Timber. *See* WOODS.

Timber Measurement. Timber in bulk is measured in units termed STANDARDS. A standard of pine is 720 ft. of 11 in. by 3 in.; boards are measured by the superficial foot, reckoning the unit thickness as 1 in.; large logs by the cubic foot; smaller stuff by the linear foot or "foot run."

Timber Rack. A place for the storage of timber, either while drying or afterwards when ready for use. In the former case the timber is always laid horizontally; in the latter it may be stored in a vertical position.

Timber Washer (*Build., etc.*) A metal washer (*q.v.*) used to prevent the heads and nuts of bolts employed in woodwork from injuring the fibre of the wood.

Timbre (*Music*). The quality of a sound, due to the form of the sound waves. A good quality of tone is comparatively rich in upper partials (*q.v.*), and the existence of these depends on the wave form. Rounded forms give a soft quality, whilst a more or less piercing quality results from angular ones. *See* HARMONICS; SOUND.

Time. All measurements of time are based on the natural units, the Day and the Year. As these are not invariable periods, MEAN TIME has been introduced. The scientific unit of time is the SECOND, which is the $\frac{1}{86400}$ part of a mean solar day. *See* MEAN SOLAR DAY, MEAN SUN, SOLAR TIME, *and* WEIGHTS AND MEASURES.

—— (*Music*). (1) The speed at which a musical composition is performed is called the time or tempo (*q.v.*) (2) The division of musical phrases into measures of equal lengths, having especial regard to the accents; the rhythm, as common time; triple time. These divisions are indicated by time signatures (*q.v.*) There are two kinds of time: (*a*) Common time; (*b*) triple time. In common time the accents occur on alternate beats, whilst in triple time they occur once in every three beats. Common time is sometimes divided into duple and quadruple time, respectively two and four beats in a bar. Both common and triple time are subdivided into simple and compound times. Compound time is formed by combining two, three, or four bars of triple time into one bar: two or four bars making compound common time, three bars making compound triple time. These are all set out in full *under* TIME SIGNATURE. Other kinds of time consist of combinations of common and triple time, *e.g.* quintuple time is formed by combining one bar of common time with a bar of triple time, thus:

or a bar of triple time with a bar of common, thus:

See TIME SIGNATURE.

Time, Beating of (*Music*). The signs by which a conductor leads a performance. These signs are generally made with a short stick, called a baton, and should be made decidedly and by a wrist movement. Flourishing the baton and all other unnecessary movements only worry both performers and audience. The following diagrams show the movement of the baton in beating different measures of time:

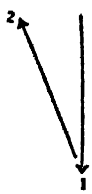


FIG. 1.—TWO BEATS IN A BAR.

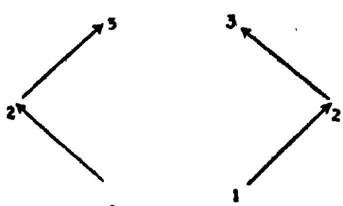

FIG. 2.—THREE BEATS IN A BAR.

The former of these is most general, and it has the advantage of being less seen by the audience than the latter, although equally visible to the performers. The latter, however, is generally used when there are performers behind the conductor. In quick triple time the beats are often given thus:

FIG. 3.—THREE BEATS IN A BAR (quick).

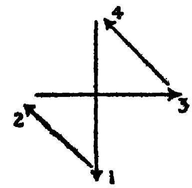

FIG. 4.—FOUR BEATS IN A BAR.

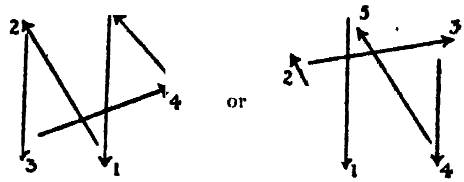

FIG. 5.—FIVE BEATS IN A BAR.

according to the place of the second accent. *See* TIME.

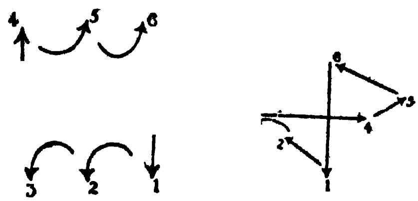

FIG. 6.—SIX BEATS IN A BAR.

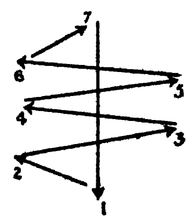

FIG. 7.—SEVEN BEATS IN A BAR.

Eight beats are given by duplicating each of the four beats, and twelve by trebling them, thus:

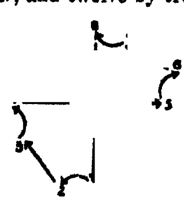

FIG. 8.—EIGHT BEATS.

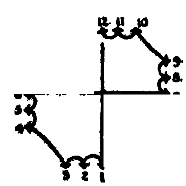

TWELVE BEATS.

Nine beats are given as in fig. 9.

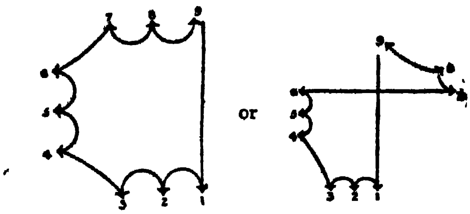

FIG. 9. NINE BEATS IN A BAR.

Timepiece. *See* WATCHES AND CLOCKS.

Time Sheets. Papers on which are recorded the hours which men have worked each day (or week) and the actual piece of work on which they were engaged. From the time sheets are compiled the wages sheets for the payment of the men, and the cost in labour of each job

Time Signature (*Music*). Signs placed at the commencement of a piece, immediately after the key signature, to indicate the rhythm in which it is written. Sometimes a change of time signature occurs during a movement, as in the following:

LISZT.

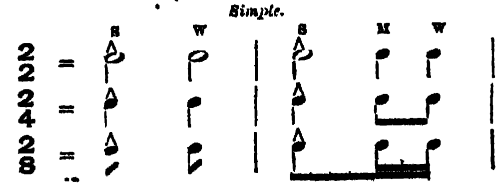
thus showing a temporary change of accent. With the exception of the signs ₵ and C, all the time signatures are denoted by figures. These figures are fractions of the semibreve (the standard note of measurement), the top figure (numerator) showing the number of beats, and the bottom figure (denominator) the kind of note of which each beat consists, *e.g.* $\frac{3}{4}$ = three-fourths of a semibreve, *i.e.* three crotchets in a bar. The signs ₵ and C are not the capital C denoting common time, but are derived from a circle. In ancient music the circle ○ denoted perfect or triple time, and the broken circle, ₵ or C, imperfect or common time. The barred ₵ denotes four minims in a bar, and is known as *Alla breve*. The C now denotes four crotchets or two minims in a bar, and is known as *Alla capella*. Both signs, however, are rapidly disappearing, and giving place to figures. The following table shows the signatures now generally in use, with their explanations and the strong, medium, and weak accents. It must be remembered that the signature shows the number of *beats* in a bar, not the number of notes:

TABLE OF TIME SIGNATURES.

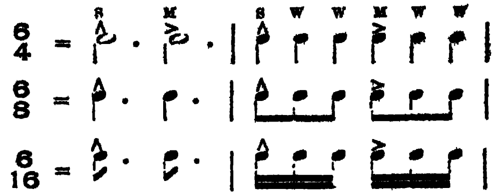
(1) *Common Time.*

(*a*) DUPLE MEASURE.

Simple.

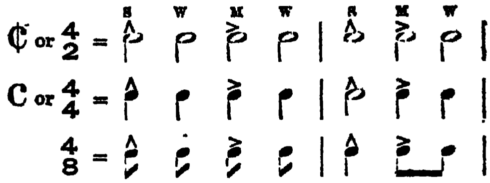


Compound.

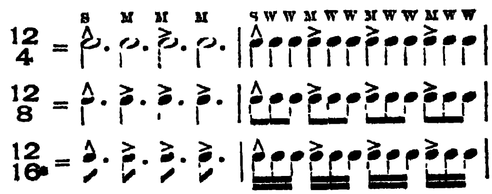


(*b*) QUADRUPLE MEASURE.

Simple.

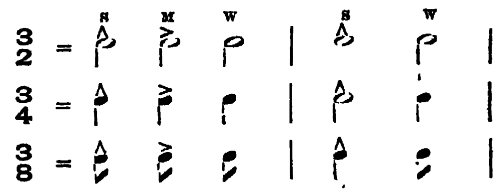


Compound.

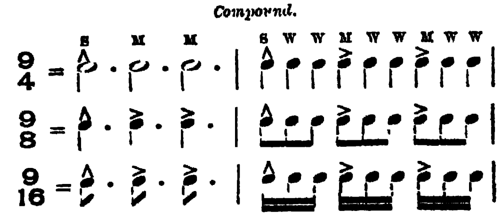


(2) *Triple Time.*

Simple.



Compound.



Other signatures may occasionally be met with, an example being given under TIME showing five crotchets in a bar. That shown above, $\frac{6}{4}$ ($\frac{3}{2}$), indicates that there are six crotchets in a bar, but having the accents on alternate crotchets—that is, a subdivision of triple time, $\frac{3}{2}$, not compound duple where the accents are on the first and fourth. In Handel's "Suite de Piece" the following combined time signatures occur in some editions:

but the same result is obtained by either writing both parts in C time and marking the groups as triplets, or by writing both in $\frac{24}{16}$ time and dotting every bass note. *See also* TIME.

Timidamente; Timore, Con; Timoroso (*Music*). Timidly; with hesitation.

Timpani, Tympani (*Music*). Kettledrums. *See* MUSICAL INSTRUMENTS, *p.* 444.

Tin (*Chem.*) Sn. Atomic weight, 119. A white metal; melts at 232°; specific gravity 7·29: very malleable, but becomes brittle at 200°. It crystallises easily: for example, by melting it, allowing part to solidify, and pouring away the still liquid part, rhombic prisms are obtained. The sound emitted by a bar of tin when it is bent is ascribed to the fracture of crystals in the interior of the bar. When tin is strongly cooled it changes to a grey powder of sp. gr. 6: this change is quickest at $-48°$. The transition point for the two forms of tin is 20°. At 20°, and even for many degrees below, the rate of change of white to grey tin is very slow: but it is greatly accelerated by putting the metal into a solution of ammonium stannic chloride $(NH_4)_2SnCl_6$, as white tin has a higher solution pressure in this than has grey tin, so that the change once started will proceed, white tin throwing out grey tin from solution. Tin is not oxidised in air at the ordinary temperature, but it is easily oxidised on heating it in air or oxygen; the dioxide is formed on complete oxidation. The action of acids is as follows: Hot strong hydrochloric acid dissolves tin somewhat readily, forming stannous chloride and evolving hydrogen. Warm dilute sulphuric acid gives stannous or stannic sulphate, according as the tin or acid is in excess, and hydrogen is evolved; but with the hot concentrated acid sulphur dioxide, sulphuretted hydrogen, and sulphur are obtained in place of hydrogen. The strongest nitric acid has no action; when sufficiently diluted it forms metastannic acid, $H_{10}Sn_5O_{15}$, probably owing to hydrolysis of previously formed stannic nitrate; the dilute acid forms stannous and ammonium nitrates. Aqua regia forms stannic chloride. Hot strong caustic soda or potash forms sodium or potassium stannate with evolution of hydrogen. Tin forms many important alloys with other metals, *e.g.* bronze, pewter, solder, gun-metal, bell-metal, Britannia metal (*see these*). It also amalgamates readily with mercury, and this amalgam was at one time largely used in making mirrors; but it is not used for this purpose now. Tin is extensively employed in the manufacture of tinplate, which is sheet iron coated with tin; the form of iron employed is rolled wrought iron or mild steel. The surface of the iron to be tinned must be very clean; it is cleaned by immersing the sheet in dilute sulphuric acid, and then polishing it with sand and water. The tinning is effected by dipping the sheet in melted tin, the surface of which is protected from air by melted fat. In reality the tin alloys with the iron, and the alloy is far less readily acted on by water than iron itself. Tin occurs chiefly as the dioxide SnO_2 (tinstone: cassiterite) (*q.v.*) To obtain tin the ore is crushed and washed with water, the stream of water carrying away much of the lighter impurity (sp. gr. tin ore = 6·5; sp. gr. rock = 2·7). The washed ore is dried and roasted; the roasting process converts sulphides to oxides, the sulphur escaping as dioxide, and it removes arsenic in the form of the volatile arsenious oxide, which is condensed in suitable chambers. If the ore contain much copper, the roasting is so conducted as to form as much copper sulphate as possible, which can be extracted with water, and the copper obtained from the solution: if it contain tungsten, this is removed by roasting with carbonate of soda in a reverberatory furnace, when a soluble sodium tungstate is formed, and is extracted with water. The ore is once more washed, mixed with powdered anthracite, and reduced by heating it in a reverberatory furnace. The crude tin so obtained is purified by placing it in bar form on the hearth of a reverberatory furnace and heating it gradually, so that the easily fusible tin separates, leaving behind a higher melting alloy of tin and other metals which are not entirely removed in the preceding processes. This easier fused product is received in an iron vessel over a fire to keep the tin melted, and poles of wet wood are plunged into it ("poling"), the object being to agitate the metal, which is then exposed to air, and the last traces of oxidisable metals removed as oxides which form a scum on the surface of the tin. When cast the product is known as block tin: when heated to the temperature at which it becomes brittle and then broken up it forms grain tin.

Tincal (*Min.*) *See* BORAX.

Tin Compounds (*Chem.*) Tin forms two oxides—stannous oxide, SnO, and stannic oxide, SnO_2. These oxides function both as basic and acid oxides. From the first are derived the stannous salts SnX_2, and the stannites M_2SnO_2; from the second are derived the stannic salts SnX_4, and the stannates M_2SnO_3. X stands for a monovalent acid radical and M stands for a monovalent metal or positive compound radical, *e.g.* NH_4. STANNOUS OXIDE is a dark crystalline powder. When heated in air it is oxidised, but not completely, to the dioxide; it is insoluble in water, but soluble in acids, forming stannous salts. When caustic potash solution, in slight excess, is added to a solution of stannous chloride, a precipitate of STANNOUS HYDROXIDE, $Sn(OH)_2$, is obtained, which when filtered and washed yields stannous oxide on boiling with water containing only a little caustic potash. The white precipitate of hydroxide obtained above dissolves in excess of caustic potash (or soda), and the resulting solution contains a stannite, K_2SnO_2. The STANNITES are reducing agents. Thus they give a black precipitate of hypobismuthous oxide Bi_2O_2 with a solution of a bismuth salt,

they reduce diazonium chlorides to hydrocarbons ($C_6H_5N_2Cl$ to C_6H_6), and they reduce nitro compounds to azo compounds ($C_6H_5NO_2$ to $C_6H_5N_2C_6H_5$). STANNOUS CHLORIDE, $SnCl_2$, is a white solid; melts at 250°; boils at 606°. Its vapour density corresponds to a mixture of Sn_2Cl_4 and $SnCl_2$ molecules except at very high temperatures, when it corresponds to that required by $SnCl_2$. Ordinarily the salt is met with crystallised in small prisms containing two molecules water of crystallisation, $SnCl_2 2H_2O$. These crystals are soluble in a little water, but excess of water hydrolyses the salt, and a basic chloride, insoluble in water, but soluble in acids, is precipitated $(Sn.OH.Cl)_2H_2O$; they are also soluble in alcohol. A solution of stannous chloride absorbs oxygen from the air, giving the basic chloride just mentioned. It is much used as a reducing agent, *e.g.* it reduces silver, mercury, gold, and platinum salts to the metal, ferric to ferrous salts, nitro compounds to amines. When stannous chloride solution containing stannic chloride is used to reduce a gold solution, a precipitate known as purple of cassius is produced which contains gold and stannic acid; but what form the union between the two takes cannot be regarded as settled. Stannous chloride unites with alkaline chlorides to form double salts such as $(NH_4)_2SnCl_4$. Stannous chloride is used under the name of tin salt in dyeing and calico printing. The anhydrous salt can be prepared by heating tin in hydrochloric acid gas, and the crystallised salt $SnCl_2 2H_2O$ by dissolving tin in hydrochloric acid and evaporating the solution. STANNOUS SULPHIDE, SnS, is obtained as a grey crystalline solid by direct union of its elements or as as a brownish black precipitate when sulphuretted hydrogen is passed into a solution of a stannous salt. It is soluble in alkaline polysulphides forming sulphostannates, *e.g.* $(NH_4)_2S_2 + SnS = (NH_4)_2SnS_3$; it is also soluble in strong hydrochloric acid. STANNIC OXIDE is a white powder which can be obtained in crystals like the natural product, but small, by heating in a current of hydrochloric acid gas; on heating it changes colour, becoming reddish brown at a high temperature: melting point unknown; insoluble in water or acids except sulphuric acid which dissolves it, but the stannic oxide is precipitated unchanged on addition of water. It is reduced to the metal by strongly heating it in hydrogen, or with carbon (*see* TIN), or easily by fused potassium cyanide. When fused with caustic soda or potash it forms stannates. Stannic oxide is obtained by roasting tin in air or by heating any of its hydrates. Under the name of putty powder it is used for polishing purposes, in making white glass and in enamelling (rendering the enamel opaque). STANNIC HYDROXIDES: The normal hydroxide $Sn(OH)_4$ (β-stannic acid) possesses both feeble basic and acid properties—it dissolves in dilute acids to form stannic salts and in alkalis to form stannates. It is very unstable, easily losing water on heating. This hydroxide is obtained by adding a solution of a neutral salt such as sodium sulphate or ammonium nitrate to a solution of stannic chloride—the chloride is hydrolysed by the water and the colloidal solution of the hydroxide is precipitated by the neutral salt. Another hydroxide, H_2SnO_3 (α-stannic acid), is obtained by adding calcium carbonate to a solution of stannic chloride or by adding hydrochloric acid to a solution of an alkaline stannate. Its properties are similar to those of the normal hydroxide. A third hydroxide known as metastannic acid $(H_2SnO_3)^n$ is obtained as a white solid by the action of strong nitric acid on tin; it has feeble acid properties, forming salts with alkalis. On heating it gives stannic oxide. It is insoluble in strong acids but combines with them, giving compounds which dissolve in pure water. SODIUM STANNATE, Na_2SnO_3 obtained as mentioned above, crystallises well from water with three molecules water of crystallisation. It is used in calico printing under the name preparing salts. STANNIC CHLORIDE, $SnCl_4$, is a colourless liquid; boils at 114°; has a normal vapour density; fumes in air. With water it unites to form several distinct hydrates—*e.g.* $SnCl_4 3H_2O$, $SnCl_4 5H_2O$, $SnCl_4 8H_2O$—all crystalline solids. It dissolves in much water with partial hydrolysis—this is shown by the fact that on distilling the solution unchanged stannic chloride passes over with the steam while stannic hydroxide separates from the boiling solution; the hydroxide also separates on allowing a dilute solution to stand. It unites with hydrochloric acid and water in nearly theoretical proportions to form the well crystallised acid $H_2SnCl_6 . 6H_2O$ (chlorostannic acids); a number of double chlorides may be regarded as salts of this acid—*e.g.* ammonium stannic chloride $(NH_4)_2SnCl_6$, which is formed by mixing solutions of the two chlorides and crystallising; it is soluble in three times its weight of water at 15°; it is used as a mordant in dyeing under the name of pink salt (*see also* TIN.) A similar compound is formed by aniline $(C_6H_5NH_3)_2SnCl_6$. Stannic chloride is easily prepared by distilling tin in a retort in a current of dry chlorine and redistilling the product over tin filings. The chloride in the form of its pentahydrate (oxymuriate of tin) is much used as a mordant in dyeing. STANNIC SULPHIDE, SnS_2 (mosaic gold) forms golden yellow leaves when obtained in the dry way, or a dull yellow powder containing hydrated stannic oxide when prepared in the wet way. The crystalline form is not soluble in hot concentrated hydrochloric acid, but the amorphous form is: both forms dissolve in alkaline sulphides forming sulphostannates,

$$SnS_2 \times (NH_4)_2S = (NH_4)_2SnS_3;$$

both forms dissolve in alkalis, forming a mixture of stannate and sulphostannate. The crystalline form is obtained by subliming a mixture of tin filings, sulphur, and ammonium chloride, when the latter alone sublimes and leaves the stannic sulphide behind; it cannot be obtained by heating sulphur and tin together, for so much heat is evolved when the reaction is started that stannic sulphide is resolved into stannous sulphide and sulphur. In the wet way sulphuretted hydrogen is passed into a solution of stannic chloride. The crystalline form is used to imitate gold. When an alloy of tin and sodium is heated with methyl iodide a colourless oil is obtained. Analysis and a vapour density determination show that it has the formula $Sn(CH_3)_4$. This tin tetramethyl yields, on treating it with iodine, tin trimethyl iodide, $Sn(CH_3)_3I$, which is also a liquid. When tin trimethyl iodide is acted on by caustic soda it yields a hydroxide, tin trimethyl hydroxide, $Sn(CH)_3OH$, which is a crystalline solid and behaves like a strong alkali. An optically active tin compound has been prepared from tin trimethyl iodide by the following series of reactions:

$$2Sn(CH_3)_3I + Zn(C_2H_5)_2 = 2Sn(CH_3)_3(C_2H_5) + ZnI$$

$$Sn(CH_3)_3(C_2H_5) + I_2 = Sn(CH_3)_2(C_2H_5).I + CH_3I$$

$$2\,Sn(CH_3)_2(C_2H_5)I + Zn(C_3H_7)_2 = 2Sn(CH_3)_2(C_2H_5)(C_3H_7) + ZnI_2$$

$$Sn(CH_3)_2(C_2H_5)(C_3H_7) + I_2 \quad Sn(CH_3)(C_2H_5)(C_3H_7)I + CH_3I$$

The tin methylethylpropyl iodide is an oil which yields a salt of α-camphorsulphonic acid on treating it with silver α-camphorsulphonate. The tin methylethylpropyl-α-camphorsulphonate is a crystalline solid showing dextrorotation. The lævorotatory salt is not obtained on concentrating the mother liquor probably owing to the great ease with which it racemises. Many other organic tin compounds are known.

Tincture (*Her.*) The heraldic term for colour. *See* HERALDRY.

Tine. The prong of a fork; sometimes the fork itself.

Tinning (*Met.*) Coating iron (or steel) with metallic tin. The plates are cleaned and dipped into baths of molten tin, which forms a thin and uniform coating over the iron, and serves to protect the latter from oxidation and to give it a bright surface.

—— (*Plumb.*) Covering the parts to be joined with a thin coating of solder.

Tin Plates (*Met.*) Thin sheets of soft iron or mild steel, which have been coated with tin by a process of dipping. The sheets are first cleaned by pickling (*q.v.*) and are then placed in a vessel or "bath" of melted tin for some time, then removed, redipped, and allowed to drain. The tin which solidifies along the lower edge is removed by the further application of heat, and the plates are then ready for sorting. This process is termed TINNING. *See also* TIN.

Tin Pyrites (*Min.*) Also termed STANNINE and BELL METAL ORE. A sulphide of tin, copper, and iron, usually with some zinc. Crystallises in the cubic system. Colour variable; grey when pure. It forms an ore of both tin and copper in localities where it occurs in sufficient abundance. Found in Cornwall and in the Erzgebirge.

Tinstone (*Min.*) A common name for CASSITERITE (*q.v.*)

Tint (*Dec.*) A colour which has been lightened by the addition of white. The word, like shade (*q.v.*) and hue (*q.v.*), is often very loosely employed. Any number of tints can be obtained from one colour by adding different proportions of white.

Tirasse (*Music*). The coupler. *See* MUSICAL INSTRUMENTS, *pp.* 442, 443.

Tire. A TYRE (*q.v.*)

T-Iron (*Eng., etc.*) Wrought iron in section the shape of the letter T.

Titan Crane (*Eng.*) An overhanging crane used in laying large blocks in the construction of breakwaters, etc. A massive truck running on rails laid along the top of the completed part of the breakwater carries a vertical axis or pivot. On this turns a large horizontal girder frame, carrying the engine and boiler at one end. Along this frame runs a travelling crane. The whole girder frame can be rotated, giving, in the case of some modern Titans, a radius of action up to 160 feet.

Titanic Acid (*Min.*) *See* ANASTASE, BROOKITE, *and* RUTILE.

Titanic Steel (*Met.*) Steel containing a small amount of the rare metal TITANIUM. It is used to some extent for cutting tools.

Titaniferous Iron Ores (*Min.*) *See* ILMENITE.

Titanium (*Chem.*) Ti. Atomic weight 48·1. Not known in pure condition. It has been obtained containing 2 per cent. of carbon by heating an intimate mixture of carbon and titanium dioxide in a carbon crucible in the electric furnace (1000 ampères and 60 volts), removing the crude metal so produced, and heating it again, mixed with titanium dioxide at the same temperature. So obtained it is a very hard white metal: melting point unknown, but over 1680°; sp. gr. 4·9; when heated in oxygen it burns, forming the dioxide; in the form of powder it burns in nitrogen at 800°, forming the nitride; heated in steam to low redness it burns and the metal becomes white hot; it burns in chlorine at 325°, forming the tetrachloride $TiCl_4$; cold dilute sulphuric acid and boiling concentrated hydrochloric acid give a violet solution and evolve hydrogen, the former quickly, the latter slowly; nitric acid slowly oxidises the metal to the dioxide. Titanuim occurs as the dioxide (*see* ANATASE, BROOKITE, RUTILE); as titanate of iron (*see* ILMENITE); as calcium titanium silicate (*see* SPHENE). Titanium belongs to the carbon group in the periodic system (*q.v.*) A few of its principal compounds are: Titanium dioxide, TiO_2, is a white powder; when heated it becomes yellow then brown; melts in the oxyhydrogen flame; insoluble in water and acids except hot concentrated sulphuric acid, with which it forms a basic sulphate. On fusion with alkalis it forms titanates. It is also known in three different crystalline forms, of which one, the natural rutile, is isomorphous with tin dioxide; this form can be obtained by heating the artificial dioxide to a white heat with borax. The dioxide can be prepared by decomposing the tetrachloride with water, neutralising with ammonia, evaporating to dryness and strongly heating the residue; or powdered rutile is fused with potassium carbonate in a platinum dish and the powdered melt extracted with dilute hydrofluoric acid; water is added and the whole is boiled and filtered hot. Potassium titanofluoride, $K_2TiF_6H_2O$, crystallises out and is purified by recrystallisation. A solution of the pure salt is precipitated with ammonia, and the titanic hydroxide filtered, washed, and strongly heated gives the dioxide. Hydroxides corresponding to the silicic acids can be obtained—viz. orthotitanic acid, H_4TiO_4, by decomposing the tetrachloride with aqueous ammonia, and metatitanic acid, H_2TiO_3, by boiling a hydrochloric acid solution of the preceding compound—they are weak acids. The titanates, *e.g.* K_2TiO_3, are obtained as mentioned under the dioxide. Titanium tetrachloride, $TiCl_4$, is a colourles liquid; boils at 136°; fumes in air; it is decomposed by water, the chlorine atoms being replaced on cautious addition of water one by one till a solution of orthotitanic acid in hydrochloric acid is obtained. Like stannic chloride it forms double chlorides with the chlorides of the alkali metals. It is obtained by passing dry chlorine over a heated mixture of the dioxide and carbon. No normal nitrate is known. A sesquisulphate, $Ti_2(SO_4)_3$, is obtained when the metal dissolves in sulphuric acid—it forms a violet solution and is oxidised by nitric acid to the normal sulphate $Ti(SO_4)_2$. Various nitrides have been obtained; the compound of composition TiN is obtained in bronze coloured masses when the dioxide is heated in nitrogen in the electric furnace (300 to 350 ampères and 70 volts)—it is hard enough to scratch diamond. A carbide is known. Titanium cyanonitride, $Ti(CN)_2Ti_3N_2$, is often found in blast furnaces—its formation is due to the use of iron ores which contain titanium dioxide.

Title, Title Page (*Print.*, *Bind.*) Usually the first page of a work, giving its name and the names of the author and publisher.

Titration (*Chem.*) *See* VOLUMETRIC ANALYSIS.

Tl (*Chem.*) The symbol for THALLIUM (*q.v.*)

Toad's Eye Tin (*Min.*) *See* CASSITERITE.

Tobacco (*Botany*). The dried leaves of *Nicotiana tabacum* (order, *Solanaceæ*) is the chief source of tobacco, but other species of *Nicotiana* are used. LATAKIA is furnished by *N. rustica*. *See* NICOTINE.

Tobine (*Silk Manufac.*) An extra warp, working independently of the ground warp, making stripe or figure, flushing or floating over several picks.

Tobin's Tube (*Hygiene*). A ventilator consisting of a vertical shaft rising to a height of about 6 ft. above the floor of a room. The air enters through a perforated grating at the floor level, and, after passing up the tube, ascends a few feet before mixing with the air of the room. The shaft should be detachable from the wall to facilitate cleansing, as it quickly becomes lined with dust and soot. *See* VENTILATION (*under* SANITATION).

Toga (*Archæol.*) The chief outer garment of the ancient Romans; a flowing wrap or mantle more voluminous than the Greek himation (*q.v.*) It was usually a woollen fabric and white in colour, but that worn by the Magistrates and the children of the nobility, *Toga prætexta*; had a deep purple border; the *Trabea* worn by the Knights (*equites*), Augurs, etc., was ornamented with purple stripes. *Toga picta*, worn by Consuls and other high officials, was adorned with stars. The toga was worn so as to leave the right arm of the wearer free. The right to wear it was exclusively the privilege of the Roman citizen. The *Toga virilis* was assumed by youths on attaining the age of fourteen. *Cf.* STOLA *and* PALLIUM.

Toggle Joint (*Eng.*, *etc.*) A combination of levers by means of which great pressure can be applied. Two rods are hinged together so as to make an obtuse angle with each other; one of these rods is attached to a fixed support or pivot, the other to the mechanism to which the pressure is to be applied. Force is applied at the junction of the two rods in such a manner as to tend to straighten the combination, *i.e.* to bring the two rods into line with each other; as the rods are brought gradually into line with each other, a great and increasing pressure is exerted at the ends. The combination is used in certain forms of press in which a great pressure but only a small amount of movement is required.

Toilet Soaps. Soaps usually of superior quality made for toilet purposes from a stock or base of ordinary hard soap, and usually moulded and scented. The stock is frequently a cold process soap, but white curd soap, cocoanut oil and rosin soaps are also used. The base is cut up into small pieces and remelted, perfume is then introduced, and in the cheaper grades the cakes of soap are simply moulded from pieces cut from the frame. In most toilet soaps, however, the process of milling is carried out, *i.e.* the soap is passed between rollers, whence it comes in fine ribbons, which are then perfumed and afterwards pressed with great force through a milling machine, from which the soap comes in the shape of a long firm bar. This is cut into pieces, which are at once moulded. The large variety of names given to toilet soaps depends principally upon the perfumes used or the colouring.

Token (*Print.*) Ten quires or half a ream of paper is a pressman's token.

Toluene (*Chem.*) $C_6H_5.CH_3$ (methyl benzene). A colourless liquid, boils at 110°, not miscible with water, smells like benzene, burns with a smoky flame. Induction sparks convert it into acetylene and hydrogen. Forms substitution products with bromine and chlorine: (*a*) when the halogen acts on boiling toluene in sunlight substitution occurs in the side chain and with chlorine; for example, benzyl chloride $C_6H_5CH_2Cl$, benzal chloride $C_6H_5CHCl_2$, and benzotrichloride $C_6H_5CCl_3$, are formed according to the amount of chlorine passed in; (*b*) when the halogens act in the absence of sunlight substitution occurs in the nucleus, ortho- and para-halogen substitution products being formed, *e.g.*  and ; (*c*) in presence of a halogen carrier bromine enters the nucleus entirely, but chlorine enters partly into the nucleus and partly into the side chain when the toluene is boiling and exposed to sunlight. On nitration with a mixture of nitric and sulphuric acids (10 parts toluene and 10·5 and 17·5 parts ordinary concentrated nitric and sulphuric acids) below 20° a mixture of nitrotoluenes is obtained (*o*—63 per cent., *m*—2 per cent., *p*—35 per cent.) After separating, washing, and drying, it is distilled under reduced pressure till 10 per cent. has passed over—the distillate is the pure ortho-compound, and the para-compound crystallises out from the residue, and can be purified by pressing and crystallisation. With sulphuric acid it yields a mixture of ortho- and para-sulphonic acids. In carbon disulphide solution toluene unites with chromyl dichloride (also in carbon disulphide solution) to form an addition product which is decomposed by water, forming benzaldehyde (Etard's reaction). Toluene is oxidised to benzoic acid by boiling with dilute nitric or chromic acids. It is reduced by heating with fuming hydriodic acid to hexahydrotoluene. Toluene is formed as a product of the dry distillation of many different substances, *e.g.* balsam of tolu (whence the name toluene), dragon's blood, wood, and coal. It is obtained on the large scale by the fractional distillation of coal tar (*see* GAS MANUFACTURE). In the laboratory it can be prepared by Fittig's reaction (*q.v.*), and by Friedel and Craft's reaction (*q.v.*)

Toluene, Toluol. *See* COAL TAR DISTILLATION.

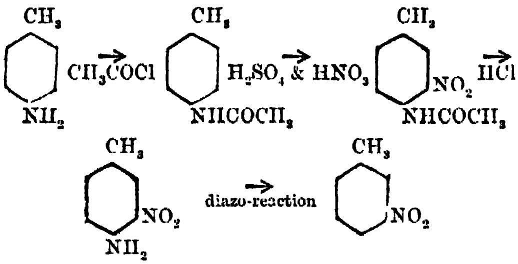
Toluidines (*Chem.*) $C_6H_4<\begin{matrix}NH_2\\CH_3\end{matrix}$ There are three of these, namely—

Orthotoluidine,  A colourless liquid, boils at 197°.

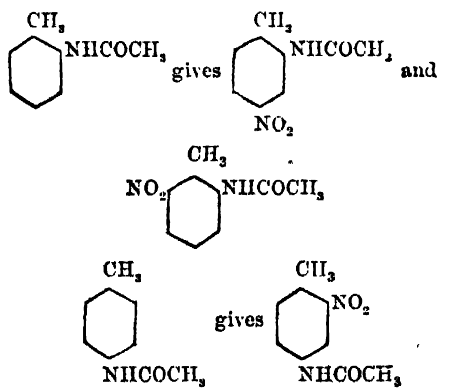
Metatoluidine,  A colourless liquid, boils at 199°.

Paratoluidine,  Shining white plates, melts at 45°, boils at 198°.

They are all obtained by reduction of the corresponding nitrotoluenes. (For the ortho- and paranitrotoluenes, *see* TOLUENE.) Metanitrotoluene is obtained by converting paratoluidine into paraacettoluidine by the action of acetyl chloride, nitrating the toluidide, hydrolysing, and then diazotising :



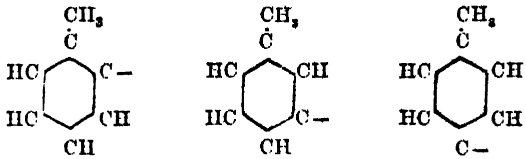
When the crude mixture of ortho-, meta-, and paranitrotoluenes (*see* TOLUENE) is reduced directly, the mixture of the three toluidines is technically known as "aniline for red" (*see* PARAROSANILINE). For some purposes the same mixture of the three is separated by partial neutralisation with oxalic or sulphuric acid and crystallisation, the orthotoluidine salts being the more soluble. The ortho- and paratoluidines are very important on account of their application in making dyes (*see* PARAROSANILINE *and* ROSANILINE). Orthotoluidine is somewhat volatile in steam; its solution in sulphuric acid is coloured blue by chromic acid; bleaching powder solution and hydrochloric acid give a violet colour; it is a weaker base than paratoluidine; it easily forms an acetyl derivative, which on oxidation with potassium permanganate gives orthoacetylaminobenzoic acid; on nitration or sulphonation the substituent takes the ortho position to the acetylamino group. Paratoluidine does not give the chromic acid and bleaching powder reactions; it readily forms an acetyl derivative, which is oxidised and substituted like the ortho-compound. When nitration of either compound is effected in presence of sulphuric acid, the nitro group enters into positions adjacent or para- to the methyl group, thus—



The toluidines undergo the diazo-reactions (*q.v.*) like aniline.

Toluylene Red (*Chem.*) *See* NEUTRAL RED.

Tolyl (*Chem.*) A name given to the residue remaining after taking away one hydrogen atom from the benzene nucleus of toluene. *E.g.*



Orthotolyl-　　Metatolyl-　　Paratolyl-.

These groups only exist in combination.

Tommy (*Eng.*) A small lever for inserting in a hole in the head of a screw, etc., to serve as a handle by which the screw may be turned.

—— (*Print.*) A small pointed steel rod used for regulating bolt headed set screws in a printing machine.

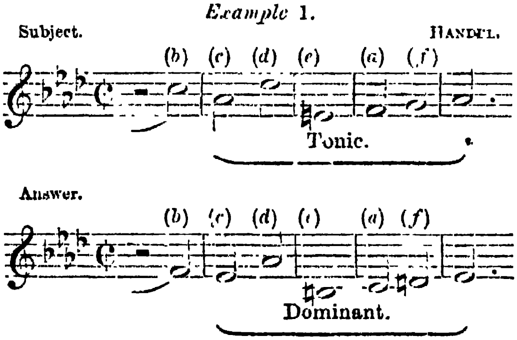
Tommy Hole (*Eng.*) The hole in which a tommy (*q.v.*) is inserted.

Ton. *See* WEIGHTS AND MEASURES.

Tonal Fugue (*Music*). A fugue that has the answer not in strict imitation, but modified in order to avoid a departure from the key tonality. *Cf.* REAL FUGUE.

EXAMPLE OF TONAL FUGUE.

Example 1.



Briefly stated it may be said that this modification is accomplished by having:

(1) The Tonic and Dominant when appearing prominently in the Subject answered respectively by Dominant and Tonic. *See* Example 1 (*a*) (*b*).

(2) The Mediant, Subdominant, and Submediant of the Tonic key answered by the corresponding notes of the Dominant key. *See* Example 1 (*c*) (*d*).

(3) That part of the subject which belongs to the Tonic key answered by the corresponding part of the Dominant key and *vice versa*. *See* Examples 1 and 2.

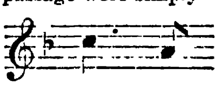
(4) Prominent intervals of a dissonant character, as *e.g.* the Diminished Seventh, etc., should be reproduced in the answer. *See* Example 1 (*e*), Example 2 (*c*).

5. The Supertonic of the Tonic key, sometimes answered by the Supertonic of the Dominant key, sometimes by the Dominant itself. Its duty in the Subject, *i.e.* whether it is the second of the Tonic key or the fifth of a Dominant key, must be carefully observed and accordingly answered. Example 1 (*f*) shows the second of the tonic answered by the second of Dominant, whilst Example 2 (*a*) (*b*) shows both

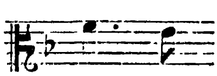
cases of the supertonic, and also further illustrations of the above rules :

Example 2.

It may be noticed that Cherubini in the second bar of Example 2 answers the Dominant by the Tonic, but treats the notes between C and A as auxiliary notes as if the passage were simply



answered by



hence the Subdominant (B) is not answered by the fourth of the Dominant (F), but by E, and the figure at the beginning of the bar left unaltered. Many exceptions to these rules may be found in the works of the great composers, but it will be observed that the exceptions are fully justified by the preservation of the character of the fugue. *See also* FUGUE, TONIC SOL-FA, *p.* 778 b.

Tonality (*Paint.*) The system of tones or colour scheme of a picture. *Cf.* CHIAROSCURO.

Tone (*Chromatics and Painting*). (1) The brightness or luminosity of a colour. (2) A quality of colour : a tint or shade. (3) The effect produced in a picture by the management of light and shade. *See* CHIAROSCURO.

—— (*Music*). (1) The interval between two sounds bearing the vibration ratio 8 : 9 as C.D., or 9 : 10 as D.E., the former being called a major tone, the latter a minor tone. A tone represents the larger steps of the scale, the smaller steps being called semitones (half-tones). *See* SCALE. (2) The quality of a sound, its timbre ; hence there is full, thin, reedy, woody, nasal tone, etc. (3) The Gregorian modes, as the 6th tone, etc.

—— (*Photo.*) The colour of a finished photograph. In some processes this is due to chemical action supplementary to producing and fixing the picture, *e.g.* the reddish hue of ordinary silver prints is altered to a more agreeable tone by means of a solution of which the principal agent is chloride of gold.

Tone (*Sound*). A single sound of definite pitch. An ordinary musical NOTE is composed of one principal tone, the FUNDAMENTAL TONE, accompanied by others, the overtones (*q.v.*)

Tones, Combination (*Sound*). *See* COMBINATION TONES.

Tonga (*Botany*). A medicinal preparation made from *Epipremnum mirabile* (*Aroideæ*) and *Premna Taitensis* (*Verbenaceæ*). Used as a specific for neuralgia.

Tongs. A form of tool used in a great variety of trades for holding objects which cannot be held in the hand. Tongs generally consist of two levers of the first kind hinged together at a point close to the jaws, *e.g.* blacksmith's tongs, crucible tongs, etc., or two levers of the third kind, connected by a spring or a hinge at the end opposite to the jaws.

Tongue (*Carp. and Join.*) (1) A projection to fit a groove. (2) A thin slip of wood, straight or cross grained, which fits into grooves ploughed in the edges of two boards which it is required to join together edge to edge.

Tongueing (*Carp., etc.*) Joining boards by means of a TONGUE (*q.v.*)

Tongue Joint (*Carp.*) A joint made by means of a TONGUE (*q.v.*)

—— (*Eng.*) A welded joint in which one piece has a V-shaped slit, the other being bevelled off so as to fit into the first.

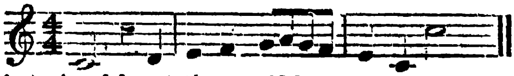
Tonic (*Music*). The technical name of the 1st degree of the scale ; the keynote.

Tonic Major (*Music*). The major scale having the same Tonic as the minor, but a different signature, as C minor, C major. *See* KEY SIGNATURE.

Tonic Minor (*Music*). The minor scale having the same Tonic as the major, but a different signature, as G major, G. minor. *Cf.* RELATIVE MINOR.

Tonic Sol-fa (*Music*). A system of musical notation, founded on a method of teaching singing by a Norwich lady, Miss Elizabeth Glover, and advanced by the late Mr. John Curwen. This system first attracted public notice in the middle of the nineteenth century, and, in order to give permanence to the system, the Tonic Sol-fa College was founded in 1869, and was incorporated in 1875. The tonic sol-fa system is adopted in a great number of elementary schools, and amongst its chief principles may be mentioned the "Movable Do" or keynote relationship—hence the word tonic, the presenting of music by letters instead of notes, with its accompanying method of indicating time duration and the teaching by mental effect and not by absolute pitch. The scales are presented in separate columns on a chart called a modulator, the scale of C being in the centre column, and the scales with flats on the left and those with sharps on the right. The tonic sol-fa method lays great emphasis on teaching from mental effect and of fixing the scale tones by chordal teaching, *i.e.* by firmly implanting the key tone and then building up in succession the notes d, m, s ; s, t, r ; and, lastly, f, l, d to complete the scale, and it is in this that the modulator is of great use. It has indeed been said that the modulator is the backbone of the system. In the centre column the major scale is shown in capital syllables Doh, Ray, Me, Fah, Soh, Lah, Te, Doh'. The melodic minor mode (scale) consists of the syllables Lah_1, Te_1, Doh, Ray, Me, Ba (pronounced Bay), Se, Lah. It will be noticed that chromatic flats are expressed by altering the vowel sound into a,

e.g. ra, ta (pronounced raw, taw), etc., and chromatic sharps have the vowel sound changed into e, *e.g.* de, fe (pronounced dee, fee), etc. Exceptions to this manner of naming occur in the following cases: Doh flat is du, fa flat is fu, me sharp is my, and te sharp is ty. The pulse (beat) always occupies the same amount of space in a composition, not as is found in the staff notation, *e.g.*

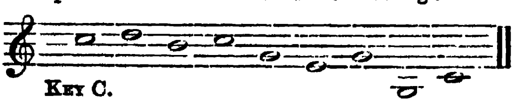


in tonic sol-fa notation would be:

KEY C.

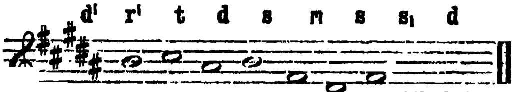
{|d :— | :r |m :f |s.l:s.f|m :d |d' :—||

It will be seen from this example that a line, —, indicates a prolonged sound, whilst a rest is indicated by a blank space. The longer upright line shows the strong pulse, the shorter upright line the medium pulse (middle of the measure), whilst the other pulses are shown by a colon. A single dot shows a pulse divided into halves, a comma into quarters, and a comma turned to the right into thirds. Doh (d) always stands for the keynote; it is therefore necessary to state the pitch of Doh at the beginning, *e.g.* key C, key F, etc. In the minor mode the key is expressed thus: Key E♭, *L* is *C*, signifying the key of C minor. When a modulation or transition of one or more removes occurs, the new key is shown, and attention called to the new tones on the right if to a sharp key, *i.e.* to the right on the modulator, thus: Key G......... A. t. m. This is called a transition of two removes (to a sharp key). If the transition is to a flat key, *i.e.* to the left on the modulator, the new tones are placed on the left, thus: Key A .... d. f. G.; or Key B .... s, d, f, D, *L* is *B*. These are respectively called a transition of two, and of three removes to a flat key. The pitch of sounds is taken from middle C (*q.v.*) to the B above according to the key; and from this note to the leading note, t. above the letters are unmarked. The octave or replicate above is written thus: d', r', m', etc., and the next octave d², r², m², etc. The octave or replicate below the unmarked octave is written d_1, r_1, m_1, etc., and the octave below this d_2, r_2, m_2, etc. The following example will show this manner of writing:



KEY C.

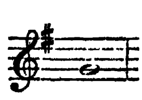
d' r' t d s m s s_1 d



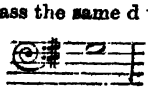
KEY B.

d r t_1 d s_1 m_1 s_1 s_2 d_1

In order to avoid unnecessary octave marks, it is customary to write tenor and bass parts an octave higher than they are—hence if d in the soprano represented



in the tenor and bass the same d would represent



The following example shows the "exposition" of Bach's Fugue in G minor in score and in tonic sol-fa notation:

Fugue No. 16.—"Das Wohltemperirte Klavier."

J. S. BACH.

KEY B♭. *Lah is G.* M. 80.

The Tonic Sol-fa College is situated in Finsbury Square, London, and consists of a president (Mr. John Spencer Curwen, M.R.A.M.), two treasurers, secretary, and a council composed of six handworkers, nine clerks and other assistants in businesses, six masters engaged in commercial pursuits, six school teachers, nine professional musicians, six fellows of the College, three ministers, three engaged in literary, scientific, or artistic pursuits, and six honorary members. Its objects are to issue certificates, grant prizes, correct exercises, deliver lectures and lessons, and for the educational improvement of the teaching of the method. W. W.

Toning (*Photo.*) Altering the colour of a print by the partial substitution of gold, platinum or some other metal for the silver of the image, or by forming a compound with it which imparts a more pleasing colour to the photograph.

Tonne. *See* WEIGHTS AND MEASURES.

Tonquin Bean (*Botany*). The fragrant seeds of *Dipteryx odorata* (order, *Leguminosæ*) are used either in the form of a powder or as an extract in perfumery.

Tool. A general name applied in trades and arts to an implement used in or by hand, as opposed to a machine; also to the actual cutting or operating portion used in conjunction with certain machines, *e.g.* the actual cutting implement or "tool" used in a slide rest lathe or planing machine.

—— (*Dec.*) A small brush used by painters and decorators, especially one for painting window sashes.

Tool Box (*Carp., Eng., etc.*) (1) A box for storing tools. (2) The part of a machine tool by which the cutting tool is actually held.

Tooled (*Bind.*) The term applied to the cover of a book that has been ornamented by means of heated tools, etc. *See* BLIND TOOLING *and* TOOLING.

—— (*Build.*) The term applied to stonework in which the tool marks on the surface are parallel, and extend across the whole width of the stone. The external surface of masonry is often finished in this manner.

Tool Holder. A CUTTER BAR (*q.v.*)

Tooling (*Arts*). Skilled work accomplished by means of a tool, especially carving.

—— (*Bind.*) The ornament effected on the cover of a book by means of heated tools, etc., either in "blind" lines (*see* BLIND TOOLING) or in gold. *See also* BOOKBINDING.

Tool Post (*Eng.*) A simple form of tool holder or tool box used in small lathes; it consists of a projection from the upper part of the slide rest (*q.v.*) having a slot in which the shank of the tool is placed, and a set screw which holds the tool firmly in place.

Tool Smith (*Eng.*) A workman who forges and tempers the metal cutting tools used in an engineering shop.

Toothed Core Disks (*Elect. Eng.*) Disks of soft sheet iron, in the circumference of which are notches which form a series of parallel grooves in armature, etc., when built up. In these grooves the conductors forming the windings are placed.

Toothed Wheels. *See* GEAR WHEELS, *etc.*

Toothing (*Build.*) The projecting bricks left at the end of a wall, in order to form a bond for a second wall which is to be built on to the former.

Toothing (*Carp. and Join.*) Roughing the surface of wide pieces of wood that are to be glued together, to enable the surface to hold the glue and produce a strong joint.

Tooth Ornament (*Architect.*) The characteristic ornament of the Early English style, generally used in hollow mouldings. It is also known as the DOG TOOTH ornament.

TOOTH ORNAMENT.

Top (*Woollen Manufac.*) *See* COMBING.

Top and Bottom Tools (*Eng.*) Swages (*q.v.*) used in shaping forgings which cannot be correctly finished by the hammer alone.

Topaz (*Min.*) A fluo-silicate of aluminium, $[Al(O,F_2)]AlSiO_4$, orthorhombic; in attached or embedded crystals of yellow, grey, or blue tints, sometimes colourless. Hardness = 8. Most of the pink topaz is produced by the slow heating of the yellow varieties. Good specimens are much used in jewellery. From several localities in Cornwall. Beautiful blue crystals from Banffshire and Aberdeenshire, the Mourne Mountains, Siberia, Ceylon, Brazil, etc. *See also* PRECIOUS STONES.

Topazolite (*Min.*) A transparent greenish garnet. *See* PRECIOUS STONES.

Top Card (*Eng.*) An indicator diagram (*q.v.*) taken from the upper end of a cylinder, or from the end nearest to the crank.

Top Face (*Moulding*). The surface of a casting which is uppermost in the mould.

Top Iron (*Carp., etc.*) The upper or non-cutting portion of the double plane iron, used in the larger planes, such as the trying jack and smoothing planes. It serves to stiffen the cutting iron and to deflect and break the shaving as it is produced by the former.

Töpler Pump. *See* AIR PUMPS.

Top Part (*Foundry*). The upper part of a moulding box or of a mould.

Topping. Taking off the points of those teeth of a saw which project too far.

Top Rail (*Carp. and Join.*) The highest rail in any kind of framing.

Top Rake. The slope of the upper surface of a tool immediately behind the cutting edge.

Toque (*Cost.*) A silk or velvet cap without a brim or with a very narrow brim, generally adorned with a plume. Worn extensively in the sixteenth and seventeenth centuries by both men and women, and at a later period in France. A conical headdress, richly ornamented, worn by the Doge of Venice.

Torbanite (*Min.*) A hydro-carbon mineral found at Torbane Hill, in Scotland, used in gas making on account of the large volume of gas it yields. Of historic interest as having given rise to a famous lawsuit to determine if it were "coal" or not.

Torbernite (*Min.*) A hydrous uranium and copper phosphate, $CuO . 2UO_3 . P_2O_5 . 8H_2O$, tetragonal; in tubular crystals of grass green colour. The crystals easily cleave into thin laminæ, hence the mineral is sometimes called Uranmica; from its composition it is also known as Copper Uranite. It contains about 60 per cent. of uranic oxide, and about 15 per cent. of phosphoric acid. From Devon and Cornwall; Saxony, Bohemia.

Torching (*Build.*) Plastering the underside of tiles on a roof, when fixed on battens.

Tornadoes (*Meteorol.*) Low pressure areas of intense energy but of limited extent. They are associated with very strong winds, and capable of doing an immense amount of damage.

Torque (*Archæol.*) A convolute metal ornament forming a collar or a bracelet. Such an ornament was worn by the Gauls round the neck and by the Anglo-Saxons on the arms.

—— (*Phys., Eng., etc.*) *See* TURNING MOMENT.

Torricellian Vacuum (*Phys.*) The vacuum above the mercury in a mercurial barometer.

Torridonian Rocks (*Geol.*) *See* PRE-CAMBRIAN ROCKS.

Torrid Zone (*Astron.*) *See* TROPICS.

Torsion. Twisting, or the effect of twisting; the term is applied especially in physics and engineering to the twisting of a piece of a material by a couple. *See* TORSION, ELASTICITY OF.

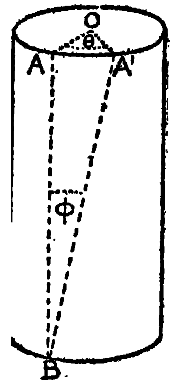
Torsional Pendulum (*Phys.*) If a heavy mass, suspended from an elastic fibre, be twisted through a small angle, and then set free, it will perform a series of simple harmonic oscillations about its position of rest. If K be the moment of inertia (*q.v.*) of the solid about an axis coinciding with the direction of the suspending fibre, and C be the restoring couple brought into play by the fibre when the mass is turned through a unit angle; then T, the time of vibration, is given by the formula

$$T = 2\pi\sqrt{\frac{K}{C}}$$

Torsional Stress. A twisting stress, or stress produced by the application of a couple (*q.v.*)

Torsion Balance (*Phys.*) An instrument for the investigation of the laws of electric and magnetic forces. The charged bodies (or poles) are at the ends of a horizontal rod, suspended by a fibre of silk, a fine wire, etc. An electric (or magnetic) force applied to the end turns the rod through an angle, and the magnitude of the force is proportional to the angle through which the top of the fibre must be turned in order to bring the rod back to the original position. In order to measure this angle, the top of the suspending fibre is attached to a graduated head, which can be turned through any required angle. An instrument on a similar principle was used by Cavendish (1797-8), in his experiments on the density of the earth; two leaden balls, 2 in. in diameter, were fixed at the ends of a rod 6 ft. long, suspended by a copper wire about 40 in. long; the attracting masses were two leaden spheres 12 in. in diameter, which could be placed nearer to, or farther from, the small spheres, thereby setting up a displacement due to the attraction between the large and small masses. The amount of this attraction was deduced from the time of vibration of the suspended system. This experiment has been repeated with a greatly improved form of apparatus by Boys (1895), the attracted masses being suspended by a fine quartz fibre.

Torsion, Elasticity of (*Phys., Eng., etc.*) If one end of a thin tube be rigidly fixed and the other end be twisted by a couple (*q.v.*) then the stress produced in the tube is of the nature of a SHEAR (*q.v.*) In the figure, the lower end of the tube is supposed to be fixed, and the upper end twisted until the line originally at O A is turned into the position O A', or through an angle θ, which is termed the ANGLE OF TORSION. Then the line B A is twisted into the position B A', or through an angle ϕ. The shear is then equal to this angle. If the actual amount of tangential force applied per unit area to the upper end of the tube be q, then we have



Coefficient of Elasticity of

$$\text{Torsion} \quad \frac{q}{\phi}.$$

This Coefficient is also termed the SIMPLE RIGIDITY. *See also* SHEAR.

In the case of a solid round bar (such as a shaft) the calculation of the coefficient depends upon dividing up the bar into imaginary concentric tubes, each of infinitesimal thickness, and then effecting a summation of the results by the Integral Calculus. This is one of the most important cases in practice: if l be the length of the shaft, r the radius, θ the angle of torsion, and T the applied couple by which the shaft is twisted, then we get the result

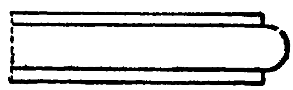
$$T = \frac{\pi r^4 \theta}{2l} C$$

That is, the Angle of Torsion is proportional to the couple which is applied, and inversely proportional to the fourth power of the radius of the shaft. Hence a small increase in diameter means a very large increase in the power of the shaft to resist torsion; if we double the diameter, we increase the resistance which the shaft offers to torsion to an amount which is sixteen times its former value.

The Simple Rigidity of some common materials is approximately:

Steel . .	8·2	10^{11}	dynes per sq. cm.
Wrought Iron	7·7	10^{11}	,, ,,
Brass . .	3·8	10^{11}	,, ,,
Quartz Fibre..	2·9	10^{11}	,, ,,

Torus (*Architect.*) A large convex moulding principally used in classical architecture.



TORUS.

Tossing (*Met.*) Oxidation of the impurities present in tin by lifting the fluid metal in ladles and pouring it back into the containing vessel; by this means the metal is exposed to the action of the air.

Tosto (*Music*). Rather. It is the equivalent of Quasi (*q.v.*)

Total Characteristic Curve (*Elect. Eng.*) *See* DYNAMO.

Total Eclipse (*Astron.*) *See* ECLIPSE, SOLAR.

Total Heat of Steam. The amount of heat necessary to raise unit mass of water from the freezing point to the temperature at which it is evaporated, and then to turn it all into steam at constant pressure. Using the pound as unit of mass and degree Fahrenheit as unit of temperature, the total heat of steam at t°F. is given by the formula

$$H = 1091{\cdot}7 + {\cdot}305\,(t^\circ - 32^\circ)$$

Using the gram and Centigrade degrees, this becomes

$$H = 606{\cdot}5 + {\cdot}305t$$

These are Regnault's values; but modern research suggests that the value

$$H = 596 + \cdot 399t$$

is probably more correct.

Total Internal Reflection (*Light*). If a ray travelling in one medium strike the surface separating that medium from one less dense, it will not emerge from the denser medium if the angle of incidence exceed a certain value. If the angle of incidence, i, be such that $\sin i = \mu$, the index of refraction from the first medium to the second, then i is termed the CRITICAL ANGLE (*q.v.*). The ray in this case passes along the surface of separation of the media. If the angle of incidence exceed i, the ray is entirely reflected at the surface of separation, the angles in this case following the laws of reflection. This phenomenon is termed TOTAL INTERNAL REFLECTION.

Total Reflection. *See* TOTAL INTERNAL REFLECTION *and* CRITICAL ANGLE.

Touch (*Plumb.*) Tallow used in plumbing.

Touch Box (*Plumb.*) A box used by plumbers to keep tallow in.

Touch Hole (*Eng.*) A name sometimes applied to the opening in the cylinder of a gas engine through which ignition is effected. *See* GAS ENGINES.

Tough Pitch. *See* COPPER *and* POLING.

Tourbillon (*Watches*). A rotary carriage containing the escapement. It turns continuously round inside the watch in some short interval of time, so that the watch records the *mean rate* of the different vertical positions, thus practically removing a troublesome source of error. *Cf.* KARRUSEL.

Tourmaline (*Min.*) A silicate of boron, aluminium, and (magnesium, iron, lithium, potash); composition very complex. Rhombohedral, with the prisms generally triangular. Colour very variable, from black (Schorl), dark blue, green, pink, to colourless. The varieties rubellite, indicolite, Brazilian sapphire, Brazilian emerald, and peridot of Ceylon are mentioned under PRECIOUS STONES. Finer varieties are used in jewellery, and are found in Ceylon, Siberia, Brazil, and Ava. Common varieties are very widely distributed.

Tourmaline Forceps (*Phys.*) A device for holding a crystal, etc., between two plates of Tourmaline (*q.v.*) which serve as a polariser and analyser respectively in simple observations on polarisation. *See* POLARISATION.

Tourney Helm (*Arm.*) A form of helmet worn in the tourneys of the fifteenth and sixteenth centuries. The face opening was large and was protected by light iron bars fixed transversely and having spaces between. *Cf.* TILTING HELMET.

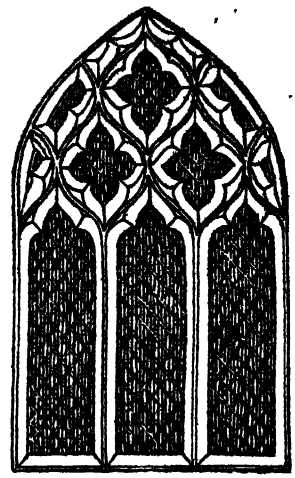
Tow (*Linen Manufac.*) In the process of dressing flax it is combed or hackled. This draws out all the short, twisted, and broken fibres, which are called Tow and are carded and spun for coarse yarns and ropes. *See* LINEN MANUFACTURE.

Town Refuse. *See* WASTE PRODUCTS *and* SANITATION.

T-piece (*Eng., etc.*) An object (*e.g.* a branching pipe) of the form of the letter T.

Trabeated (*Architect.*) (1) A style of architecture in which columns and lintels are the principal structural features. (2) Furnished with an entablature.

Tracery (*Architect.*) The ornamental pierced stonework in the head of a Gothic window. The same name is also given to similar work executed in stone or wood in canopies, etc. *See* BAR TRACERY, PLATE TRACERY, *and* FLAMBOYANT TRACERY.



TRACERY.

Trachyte (*Geol.*) Eruptive rocks of sub-acid composition (60 to 65 per cent. of silica) which have consolidated under smaller pressure than the corresponding plutonic rock of similar chemical composition (syenite), and therefore are not entirely crystalline throughout. The chief minerals occurring in Trachytes are Orthoclase, and certain other Felspars (*q.v.*), Hornblende, and sometimes Augite, Mica, Magnetite, etc. Quartz sometimes occurs; the rock is then termed a QUARTZ TRACHYTE.

Tracing. A copy of a drawing made on transparent paper or tracing cloth (*q.v.*), which is laid over the original, the lines being then drawn exactly over those of the original drawing.

Tracing Cloth. Smooth transparent linen on which a tracing (*q.v.*) is made. It is sized on one side.

Tracing Machine (*Joinery, etc.*) A machine for cutting or carving ornamentation on woodwork. A cutter is carried on the end of a swinging arm which is guided by some form of template; this cutter roughs out the carving very rapidly and with very little attention.

Tracing Paper. Ordinary unsized paper coated on one side with a varnish of Canada balsam and turps, or treated with wax; used for making a tracing (*q.v.*).

Track Circuit Signalling (*Civil Eng.*) *See* RAILWAYS.

Tracker (*Music*). A thin flat or round strip of wood used in the mechanism of the organ, for pulling the pull-down wire or for conveying leverage from one part to another. *See* ORGAN, *p.* 439. The tracker differs from the sticker in having to pull whilst the sticker always pushes. For this reason each end of the tracker is provided with a screw which when being passed through the backfall or roller arm or other lever is held in position by a leather button.

Traction (*Eng.*) The drawing or pulling of vehicles along a road or track. *See also* ELECTRIC TRACTION *and* RAILWAYS.

Traction Engine (*Eng.*) A form of locomotive adapted for use on common roads. The most usual form has a boiler of the locomotive type (*see* BOILERS) on top of which is mounted a horizontal engine with one or two cylinders. The engine is carried on four wheels, the two front ones being small and mounted on a bogie under the smoke box, so that by turning the bogie by means of suitable gear the engine can be steered. The hind wheels are large, and the motion of the engine is transmitted to one of them by means of toothed wheels. These wheels can be thrown out of gear, so that the engine can be used as a stationary engine when required, the power being taken from the crank shaft of the engine, which is provided with a driving pulley. A heavy flywheel and a governor are also fitted, completing the equipment necessary for a stationary engine, as distinguished from a locomotive.

Tractive Force (*Eng.*) The force necessary to draw a vehicle on a level surface, *i.e.* to overcome frictional resistance.

Trade Wastes. *See* WASTE PRODUCTS.

Trade Winds (*Meteorol.*) Prevailing winds occurring in tropical regions, due to the rush of cold air from cooler zones lying to the north and south. If the earth were at rest, these winds would blow nearly due N. and S., but in consequence of the earth's rotation they are displaced and appear to come from the N.E. and S.E.

Tragacanth, Gum Dragon, *or* **Gum Tragacanth** (*Botany*). A natural exudation of gum from the bark of the stem of several spiny shrubs of the genus *Astragalus* (*Leguminosæ*). Native to Asia Minor and the surrounding districts. Used in pharmacy, in the textile trades, and as a mucilage in marbling the end papers and edges of books. *See* GUMS.

Trailing Axle, Springs, Wheels, etc. (*Eng.*) The hinder axle, wheels, etc., of a locomotive, *i.e.* the wheel, etc., situate behind the driving wheels.

Trailing of a Dyke (*Geol.*) *See* HEAVES.

Trails (*Astron.*) If a camera be pointed to the sky on a dark and clear night, the images of the stars on the photographic plate will not be points but arcs, called STAR TRAILS. Shooting stars also leave trails in the sky for a few seconds.

Train (*Clocks and Watches*). A system of toothed wheels and pinions. In ordinary clocks and watches the slowest, or first wheel of the train counting from the motive power, is called the MAIN or GREAT WHEEL; the second wheel of the going train usually carries the minute hand and is called the CENTRE WHEEL. (In those required to go longer than the usual periods, one or more wheels and pinions are interposed between the great wheel and centre pinion; these are called INTERMEDIATE WHEELS and PINIONS.) The centre wheel drives the third pinion to which the third wheel is fixed; this latter drives the fourth pinion which carries the seconds hand and turns once per minute. In clocks, the fourth pinion generally carries the escape wheel, but in watches, with their more rapid vibrations, the fourth wheel drives the escape pinion to which the escape wheel is fixed.

—— (*Eng.*) A set of moving parts connected together; *e.g.* a set of toothed wheels gearing together.

Train of a Comet (*Astron.*) *See* TAIL OF A COMET.

Train Oil. A term commonly applied to the oil obtained from the blubber of the Right Whale (*Balæna*), and from certain other species. It is used for lubrication, but is greatly inferior to sperm oil.

Tram (*Mining*). A box-like four wheeled vehicle running on tram lines; used for transporting coal below the surface of a coal mine, or for conveying it from the pit mouth to the place of shipment. *Also termed* CORF, SKIP, *and* TUB.

—— (*Silk Manufac.*) Silk doubled and lightly spun, used for weft purposes. *Cf.* ORGANZINE

—— *or* **Tram Car** (*Civil Eng.*) A vehicle provided with flanged wheels running on a tramway (*q.v.*) It is drawn by horses, a cable running in a slotted conduit, or by electric power. *See* ELECTRIC TRACTION.

Trammels (*Eng., etc.*) The holders for the pencil and compass points used in beam compasses (*q.v.*) They can slide along a wooden bar, and can be fixed in any suitable position by means of set screws.

Tramway (*Civil Eng.*) A track formed by rails laid flush with the surface of the road along which they run, in order to permit the use of the road by ordinary traffic, as well as by vehicles running on the rails. The sleepers, if used, are entirely below the surface, and are commonly longitudinal; but the rails may be laid direct on a concrete foundation, the wide flat base providing sufficient support.

Tranquillo (*Music*). Quietly, calmly.

Transepts (*Architect.*) The parts of a cruciform church forming on plan the arms of the cross.

Transfer Printing (*Pot.*) Printing by transfer may be either from copper plate or from lithographic stone. The design is first either engraved upon the copper plate or drawn upon the stone; it is then printed upon thin paper. The paper is laid print downwards upon the ware, to which the print adheres and the paper is washed off, leaving the print "transferred" to the ware.

Transformation of Energy. The energy of a body or system, that is, its capacity for doing work, may exist in a variety of forms—*e.g.* Mechanical Energy, Chemical Energy, Thermal Energy, Electrical Energy. In general, energy can be changed from one of these forms to another—for example, the burning of coal or gas produces heat (thermal energy), which may be converted by an engine into mechanical energy, and the mechanical energy may be converted by a dynamo into electrical energy. The electrical energy may in turn be converted into mechanical energy, as when the current is employed to drive a motor; or it may be converted into heat (thermal energy) if the current be used for heating or lighting; or it may be converted into chemical energy by using the current to electrolyse some chemical compound.

The following table indicates some of the methods by which the changes from one form of energy to another may be effected. Each process or method quoted is the one by which the form of energy corresponding to the *line* in which it occurs may be converted into the form given at the head of the *column*. Certain cases of transmission of energy are added for the sake of comparison; these are indicated in the table

in italics, as they are not in the proper sense instances of the transformation of energy. It will be observed that no instances of the transformation of chemical energy into mechanical energy, and *vice versâ*, are given, as no cases of *direct* transformation are known. Chemical energy is obviously capable, however, of transformation into heat energy, and thus in turn into electrical or mechanical energy.

	Mechanical energy.	Thermal energy.	Electrical energy.	Chemical energy.
Mechanical energy	*Machines in general (transmission of energy).*	Friction, compression, percussion.	Electrical machines (friction and influence), dynamos.	?
Thermal energy .	Steam and gas engines: explosions, etc.	*Conduction (transmission of energy).*	Thermo-electric couples.	Production of endothermic compounds.
Electrical energy .	The mechanical effects produced by magnets, electric currents, electrical discharge, etc.	Heating effects of the electric current or discharge.	*Transformers (transmission of energy).*	Electrolysis: the process of charging accumulators.
Chemical energy .	?	Production of heat by chemical action.	Primary cells: discharge of accumulators.	Chemical actions in general.

Transformers (*Elect.*) A transformer is a device by which a small current at a high voltage or "pressure" is converted into a larger current at a lower voltage. In the majority of cases both these currents are alternating currents of the same frequency, and the apparatus then used is the ordinary ALTERNATE CURRENT TRANSFORMER. This consists in its simplest and most typical form of a CORE built up of thin plates of soft iron so as to produce a continuous magnetic circuit, and is usually in the shape of a rectangular frame. On this core are wound the PRIMARY and SECONDARY COILS, the number of turns of wire in the two coils being approximately proportional to the voltages of the primary and secondary currents. Thus, if a primary current at 2,000 volts is to be transformed into a current at 100 volts, the ratio of the turns in the two coils will be about 20 to 1. The action of the transformer depends upon the periodic change in the magnetic flux in the core which is induced by the variations of the primary current. As the same flux passes through the secondary coil, an E.M.F. is thereby set up in this coil, giving rise when the secondary circuit is completed to an alternating current of the same frequency as the primary current. The efficiency of a good transformer is very high, the total loss of energy being in some cases not more than 3 or 4 per cent. The chief sources of loss are: (1) Hysteresis (*q.v.*); (2) Eddy or Foucault Currents (*q.v.*); (3) Resistance of the windings. In each case the lost energy appears in the form of heat, which raises the temperature of the transformer, and is ultimately radiated from its surface. Cooling is sometimes aided by immersing the apparatus in oil. Another class of transformers are more often termed CONVERTERS or ROTARY CONVERTERS; they are used in the transformation of alternate currents to continuous currents (or *vice versâ*), or for changing the voltage of continuous currents. In the first case, an alternating current motor drives a continuous current dynamo (or *vice versâ*); in the second case, both dynamo and motor are of the continuous current type. In certain forms there is but one field magnet and one armature, the latter carrying two sets of windings.

Transit (*Astron.*) The crossing of the meridian by any celestial body. Also applied in a special sense to the passage of one celestial body in front of another, *e.g.* the passage of the planets Mercury or Venus in front of the sun.

Transit (*Surveying*). The term used in America for the Transit Theodolite (*q.v.*)

Transit Circle (*Astron.*) A telescope turning on a horizontal axis fixed due east and west, so that the instrument always points to the meridian. A large vertical graduated circle is fixed to the telescope so that the north polar distance, or altitude, or declination of the body under observation can be determined. *See* MERIDIAN CIRCLE.

Transition (*Architect.*) A period in architectural history during which a change from one style to another is progressing. The term is generally used to denote the transition from the Romanesque to the Gothic. *See* DECORATED.

—— (*Music*). A change of key. It is usually used to denote a *temporary* modulation.

Transition Elements (*Chem.*) A name given to the elements of Group VIII. of the PERIODIC SYSTEM (*q.v.*)

Transit Theodolite (*Surveying*). A theodolite in which the telescope is capable of complete rotation round its horizontal axis, movement in this plane being limited in other forms. *See* THEODOLITE.

Transmission Gratings (*Light*). *See* DIFFRACTION GRATINGS.

Transmission of Power. Power is transmitted or communicated from place to place in a great variety of ways; but in engineering phraseology the above term usually refers only to the transmission of actual motion. This is effected by shafts, belts, cables, etc. Power may also be transmitted by means of fluids under pressure (hydraulic transmission), by means of electric currents, etc. Steam engines may also be worked at a considerable distance from their boilers if the pipes are well coated with non-conductors, and compressed air motors are almost invariably placed a long way from the compressors which supply the air by which they are driven.

Transmitter (*Elect.*) The apparatus employed in sending a message either by the TELEGRAPH or TELEPHONE (*q.v.*)

Transom (*Build.*) The horizontal member of a frame between the head and sill, *e.g.* a horizontal timber crossing the frame of a door below the fanlight; the crossbar or horizontal member of a mullion window.

—— (*Eng.*) A transverse piece of timber serving as a strut between two parallel members, *e.g.* between longitudinal sleepers.

Transporter (*Eng.*) An appliance for moving material in bulk, or large numbers of separate objects, from place to place without the aid of manual labour; more often termed a CONVEYOR. The material may be carried on broad belts, or a series of buckets running on chains, the whole machine being driven by power.

Transpose (*Typog.*) In imposing, to place the pages in wrong order. This word, or more generally its abbreviated form *trs.*, written in the margin of a proof signifies that a word, line, or other portion of printed matter indicated is to be transferred to another position. *See p.* 568.

Transposing Instruments (*Music*). Are divided into those which transpose (1) an octave, such as the Double-bass, Contra-bassoon, and Piccolo; (2) some interval other than the octave (or at times the octave) such as the Clarionets, Basset Horn, Saxophones, some Oboes, Cor Anglais, some Flutes, some Piccolos, Horns, Trumpets. The exact transposition in each instance is given under the article MUSICAL INSTRUMENTS, *pp.* 426-38.

Transposition (*Music*). A change of pitch, or clef. In transposition every interval of a musical passage is reproduced either at another pitch, that is, (1) in another key as at Example 1, or (2) at the interval of an octave in the same key as at Example 2, or (3) in another key practically at the same pitch, as at Example 3; this last is known as enharmonic transposition (*see* ENHARMONIC), or (4) from one clef to another at the same pitch as at Example 4.

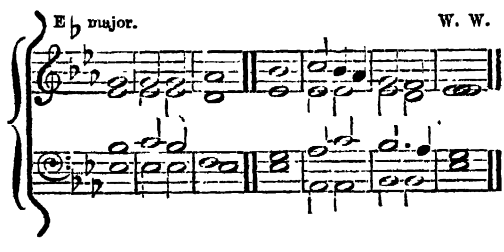
EXAMPLE 1.—TRANSPOSITION IN NEW KEY; AN AUGMENTED SECOND ABOVE.

EXAMPLE 2.—TRANSPOSITION AN OCTAVE BELOW, AND IN ANOTHER CLEF.

EXAMPLE 3.—ENHARMONIC TRANSPOSITION.

EXAMPLE 4.—FROM ONE CLEF TO ANOTHER AT THE SAME PITCH.

Transposition is also used to change a passage from a major to a minor mode, or *vice versa*, as in the following example:



See also TRANSPOSING INSTRUMENTS.

Transverse Section. A section (*q.v.*) across an object, *i.e.* at right angles to the longitudinal axis or direction of greatest length.

Trap (*Sanitation*). In its simplest form a trap is a bend in a pipe which retains water that is automatically replaced whenever the trap is used, thus preventing the return flow of noxious gases. The trap most commonly used is the Siphon Trap (*q.v.*) The essentials of a good trap are: (*a*) an efficient water seal, *e.g.* in the siphon trap the water should stand at least three-quarters of an inch above the openings of the bend; (*b*) the trap should be self-cleansing; (*c*) every portion should be effectually cleansed by each flush. Other more or less efficient traps are the Midfeather (*q.v.*); the bell trap, a modification of the foregoing; and the ball trap, or Cousler's trap, in which a ball rises with the rise of water in the sewer and closes the aperture. In the case of traps to water closets, a ventilating pipe is generally connected with the outer side of the trap to prevent siphoning. *See also* SANITATION.

—— (*Weaving*). The term applied to a breakage of warp threads in a loom through faulty working.

Trapezium. A plane figure having four unequal sides, no two of which are parallel.

Trapezoid. A plane four sided figure having two sides parallel.

Trappean Rocks (*Geol.*) Eruptive or igneous rocks, which have consolidated below the surface of the ground, though not at the greatest depths as in the case of Plutonic Rocks (*q.v.*) The name is derived from the Swedish word *Trappa* (a flight of steps), which was applied owing to the steplike form in which these rocks frequently occur.

Travel (*Eng.*) The distance through which a part of some mechanism can move in a straight line.

Traveller (*Cotton Spinning*). In Ring spinning, a small metal loop or ring which guides the yarn when being wound upon the spindle. *See* RING FRAME.

—— *or* **Travelling Crane** (*Eng.*) *See* CRANES.

Traverse (*Surveying*). A series of consecutive lines, the directions and lengths of which have been ascertained.

——, **Traverse Net** (*Lace Manufac.*) A term applied to John Heathcote's traverse Brussels net; it also applies to other nets and laces where certain threads are traversed or laid crosswise over a more limited area.

Traverse Tables (*Surveying*). Tables which show by inspection the co-ordinates of any point in a traverse.

Traversing (*Eng.*) The ordinary operation of turning in a self-acting lathe, in which the tool moves longitudinally, as opposed to Surfacing (*q.v.*), in which the tool travels across the bed. The term "traversing" is also applied to various longitudinal movements in machine tools and other mechanism.

Traversing Bridge (*Civil Eng.*) A bridge formed by a girder like structure, which can be drawn backward by hydraulic or other power, in order to furnish an opening through which vessels can pass. Examples occur in the Millwall Docks and also at Barry.

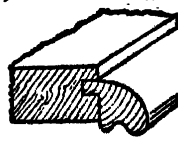
Traversing Mandrel (*Eng.*) A lathe mandrel (*q.v.*) which is capable of longitudinal motion. This motion is usually communicated to the mandrel by means of a short screw attached to the mandrel; the screw runs through a nut fixed to the headstock, and therefore the mandrel advances in each revolution through a distance equal to the pitch of the screw. If a piece of metal held in a chuck be acted upon by a tool which is kept fixed, a screw thread will be cut upon it, of pitch equal to that of the screw fixed to the mandrel. This device is very convenient for cutting small screws and for ornamental and fancy turning.

Traversing Screw (*Eng.*) A screw employed for producing a longitudinal motion; the leading screw of a lathe is a particular example.

Traverso (*Music*). Crossways. *See* FLUTE *under* MUSICAL INSTRUMENTS, *p.* 434.

Travertine (*Geol.*) Calcareous rock formed by the deposition of carbonate of lime, together with other materials, by underground water.

Treacle Moulding (*Joining*). A moulding of the form shown in the figure.



TREACLE MOULDING.

Tread (*Build.*) The part of a stair or step on which the foot rests.

—— (*Eng.*) The bearing surface of a wheel on road or rail. The parts of the surfaces of a rail and a wheel which come in contact with each other are termed the Tread of the Rail and the Tread of the Wheel respectively.

——, **Width of** (*Cycles*). The distance between the two inner flanges of the pedals, measured in a line parallel to the crank axle.

Treadle. The lever on which the foot is pressed, in order to communicate motion (not necessarily rotary) to a machine.

Treadle Machine (*Print.*) A small printing machine of the platen order, worked by the foot of the operator.

Treble (*Music*). (1) The name given to the clef which was originally written as the letter *g* or G, now written  on the second line of the stave. *See* STAVE *and* SCORE. (2) The name given to soprano voices, especially boys'.

Treble Geared Lathe (*Eng.*) A lathe having back gear (*q.v.*), in which three wheels and three pinions are used, so that the velocity of the mandrel is reduced to a still greater extent than by ordinary back gear.

Trebles (*Met.*) Sheet iron of gauge varying from Nos. 25 to 27 of the Birmingham Wire Gauge. *See* WIRE GAUGES.

Tre Corde (*Music*). Without the left pedal. *Cf.* UNA CORDA.

Tree Calf (*Bind.*) A brown calf binding which has been stained to imitate a conventional tree-like pattern.

Treflée (*Her.*) *See under* CROSS *and* TREFOIL.

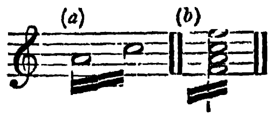
Trefoil (*Architect.*) A cusped opening in Gothic tracery formed with three foils or spaces between cusps. *See* FOIL, CINQUEFOIL, QUATREFOIL, MULTIFOIL, CUSP, *and* TRACERY.

—— (*Her.*) A leaf having three cusps like a clover leaf. Treflée indicates adorned with Trefoils.

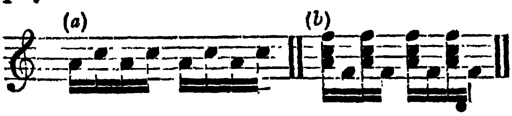
Tremolite (*Min.*) A calcium magnesium Amphibole (*q.v.*) $3MgO \cdot SiO_2 \cdot CaO \cdot SiO_2$. In long bladelike crystals of a greyish or white colour. Also in fibrous and columnar masses. From Switzerland and many places where there are metamorphic rocks.

Tremolo (*Music*). In a tremulous manner. Tremolo may be divided into reiterated notes played as rapidly as possible, and written thus:

and into divided chords played quickly and written thus:



played—



Tremulant *or* **Tremolo** (*Music*). Mechanism in the organ and harmonium, which acts on the supply of wind in such a manner as to disturb the steadiness of the supply, thus causing a throbbing sensation. Tremulants are of many patterns.

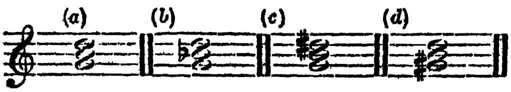
Trenail *or* **Treenail** (*Eng.*) Wooden spikes used to fix railway chairs to the sleepers; the timber from which they are made is dried and compressed, so that the subsequent swelling holds the trenails firmly in position.

T-Rest *or* **Tee-Rest** (*Eng., etc.*) The T-shaped support for a tool used in hand turning.

Trestle Bridges (*Civil Eng.*) Bridges usually at a high level, carried on timber or iron supports resembling ordinary trestles in form. They are of great use in accelerating railway construction, but are in many cases replaced by more permanent structures when the line is in full working order.

Trestles. A form of stool with a long narrow top, and four (rarely three) legs spreading out towards the base.

Triad (*Music*). A chord consisting of three notes a third above each other. A triad may be: major (*a*), minor (*b*), augmented (*c*), diminished (*d*). The first two are perfect, having the extreme notes a perfect fifth apart, the last two, not having a perfect fifth, are called imperfect.



Triad Elements (*Chem.*) Same as trivalent element. *See* VALENCY.

Trial Level (*Civil Eng.*) A preliminary measurement of the general elevation of ground along which a railway, canal, etc., is to be constructed.

Triangle (Triangolo) (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 445.

Triangle of Forces. If three forces lying in a plane be in equilibrium, they may be represented in magnitude and direction by the sides of a triangle. *Cf.* POLYGON OF FORCES *under* GRAPHIC STATICS.

Triangular Rule *or* **Scale.** A rule or scale consisting of a bar of wood whose cross section is a triangle, with suitable graduations on each face.

Triangulation (*Astron.*) The application of trigonometry to the determination of distances.

—— (*Surveying*). The method of making a survey by taking the angles to other stations from the ends of the base line, and then from these stations to further ones, thus covering the area with a network of imaginary triangles all the angles of which have been measured. From the known length of the base line, the sides of the triangles can then be calculated.

Trias (*Geol.*) The system at the base of the Secondary Rocks (*see* STRATA, TABLE OF, *in Appendix*). The name is derived from the triple division of the system, as it occurs in its most typical form, in Germany; in England one of these divisions is absent, the two existing divisions being the UPPER TRIAS or KEUPER and the LOWER TRIAS or BUNTER.

Triatomic Molecule (*Chem.*) An elementary molecule containing three atoms of the element. The only known example is Ozone (*q.v.*)

Triblet (*Eng.*) (1) A round rod or mandrel, which is put through the hole in a nut, etc., while it is being finished by a blacksmith. (2) A mandrel on which tubing is drawn.

Triboluminescence (*Phys.*) The production of luminescence by friction, as when a lump of sugar is crushed in the dark. This property is possessed by many crystals, *e.g.* Diamond, Quartz, and Uranium Nitrate.

Tributyrin (*Chem.*) $\begin{array}{l} CH_2OOC \cdot C_3H_7 \\ | \\ CHOOC \cdot C_3H_7 \\ | \\ CH_2OOC \cdot C_3H_7 \end{array}$ (Glyceryl tributyrate).

An oil; boils at 285°. Said to occur in butter, but it is probable that one or two of the butyric acid residues are replaced by higher fatty acid residues in butter fat, so that tributyrin itself is not present. It can be obtained by prolonged boiling of glycerine and butyric acid.

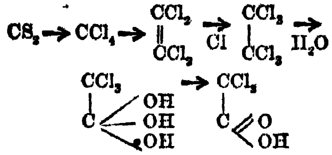
Trichloracetaldehyde (*Chem.*) A synonym for CHLORAL (*q.v.*)

Trichloracetic Acid (*Chem.*) $\begin{array}{l} CCl_3 \\ | \\ COOH \end{array}$ A white crystalline solid; melts at 52°; boils at 195°; deliquescent and very soluble in water. It has a pungent smell; it is an antiseptic and caustic, blistering the skin. Trichloracetic acid is a powerful acid, comparable in strength with the strongest mineral acids. Potassium amalgam converts its aqueous solution into acetic acid. Alkalis convert it into chloroform.

$$\begin{array}{l} CCl_3 \\ | \\ COONa \end{array} + HONa = CCl_3H + CO(ONa)_2$$

It is synthesised as follows: Carbon disulphide is

converted into carbon tetrachloride by the action of sulphur chloride in presence of iron; the carbon tetrachloride, when passed through a red hot tube, gives tetrachlorethylene; the latter exposed to sunlight in presence of chlorine and water gives trichloracetic acid:



It can be obtained by direct chlorination of acetic acid, or by oxidising chloral hydrate with fuming nitric acid.

Trichord (*Music*). Three strings. A modern pianoforte is called a trichord pianoforte because the majority of the notes have three strings each, tuned in unison. *See* PIANOFORTE, *p.* 430.

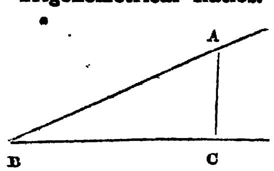
Tridymite (*Min.*) An oxide of silicon, SiO_2, occurring in small hexagonal plates in trachyte in Antrim and on the Rhine. *Cf.* QUARTZ.

Triforium (*Architect.*) *See* CLERESTORY.

Triglyphs (*Architect.*) The structural part of the frieze in a Doric entablature. There are two vertical grooves on the face of each triglyph, and a chamfer or half groove on each edge. *See* ENTABLATURE; METOPE; ARCHITECTURE, ORDERS OF; DORIC; DIGLYPH; DITRIGLYPH; *and* MEROS.

Trigonometer (*Surveying*). An instrument used in plotting a survey and by means of which the coordinates of a point, whose distance and bearing have been determined, may be read off.

Trigonometrical Ratios. Let θ be any angle; then if a line AC be drawn perpendicular to BC, the following terms are applied to the ratios between the sides of the right-angled triangle thus formed.



1. $\dfrac{\text{Perpendicular}}{\text{Hypothenuse}} = \dfrac{AC}{BA}$ termed the SINE of angle θ.
2. $\dfrac{\text{Base}}{\text{Hypothenuse}} = \dfrac{BC}{BA}$ „ „ COSINE „ „
3. $\dfrac{\text{Perpendicular}}{\text{Base}} = \dfrac{AC}{BC}$ „ „ TANGENT „ „
4. $\dfrac{\text{Hypothenuse}}{\text{Perpendicular}} = \dfrac{BA}{AC}$ „ „ COSECANT „ „
5. $\dfrac{\text{Hypothenuse}}{\text{Base}} = \dfrac{BA}{BC}$ „ „ SECANT „ „
6. $\dfrac{\text{Base}}{\text{Perpendicular}} = \dfrac{BC}{CA}$ „ „ COTANGENT „

In mathematics these ratios are abbreviated to *sin θ, cos θ, tan θ, cosec θ, sec θ, cot θ* respectively. The difference between unity and the cosine of an angle is termed the VERSED SINE (abbreviated *versin θ*), *i.e. versin* $\theta = 1 - \cos\theta$. Tables of these ratios are published, giving their values up to seven places of decimals. Their properties are dealt with in works on trigonometry.

Trigonometry. The branch of mathematics dealing with the properties of triangles and the measurement of angles.

Trihedral Angle. The figure formed by three planes which meet at a point.

Trihydric Alcohols and Phenols (*Chem.*) Alcohols and phenols containing three hydroxyl groups. For an example of a trihydric alcohol *see* GLYCERINE; for a phenol *see* PYROGALLOL *and* PHLOROGLUCIN.

Trill (*Music*). *See* ORNAMENTS (*Music*).

Trilobites (*Geol.*) An important group of fossils occurring in the Lower Palæozoic Rocks; so called from the division of the fossil into three distinct areas by two longitudinal furrows. The exact zoological position of the Trilobites is difficult to determine, but they belong to the *Arthropoda*, the Sub-Kingdom which includes the *Crustacea* (Crabs, Lobsters), *Arachnida* (Spiders), etc. Some of the chief Trilobites and the geological systems to which they belong are as follows:

CAMBRIAN SYSTEM.

Paradoxides.	*Microdiscus.*
Olenus.	*Psilocephalus.*
Agnostus.	

ORDOVICIAN SYSTEM.

Asaphus.	*Æglina.*
Ogygia.	*Calymene.*
Phacops.	*Trinucleus.*
Ampyx.	

SILURIAN SYSTEM.

Phacops.	*Chierurus.*
Homalonotus.	*Harpes.*
Calymene.	

A few Trilobites also occur in the DEVONIAN and CARBONIFEROUS SYSTEMS.

Trimethylamine (*Chem.*) $N(CH_3)_3$. A gas; boils at 3·5°; smells strongly of fish; very soluble in water; readily inflammable. It is a strong tertiary base uniting with acids to form salts, and with alkyl iodides to form quaternary ammonium compounds (*q.v.*) Examples:

$N(CH_3)_3HCl$.	$\{N(CH_3)_3 . H\}_2PtCl_6$	$N(CH_3)_4I$
Trimethylamine hydrochloride.	Platinum chloride double salt.	Tetramethyl ammonium iodide.

Trimethylamine unites directly with carbon disulphide, forming $CS_2 . N(CH_3)_3$ with evolution of heat. Trimethylamine occurs in herring brine, in some blossoms such as hawthorn and pear, in a number of plants, *e.g.* stinking goosefoot, in putrifying flesh of the most various kinds, in Gorgonzola cheese, and sometimes in urine. It can be obtained in quantity from the "vinasse" of the beetroot sugar industry. In this industry the molasses are fermented for alcohol which is distilled off; the residual liquid ("vinasse") is evaporated to dryness, and the dry residue distilled. The distillate is neutralised with sulphuric acid, and again distilled; the residual liquid consists largely of the sulphates of ammonia and trimethylamine, which can be partially separated by crystallisation, the former sulphate being the less soluble. The mother liquor is distilled with quicklime, and the distillate received in hydrochloric acid. The two hydrochlorides can be partially separated by crystallisation, ammonium chloride being the less soluble. The mother liquor is boiled down till its boiling point reaches 200°—the residue is trimethylamine hydrochloride. When methyl iodide is heated

with alcoholic ammonia in closed vessels, tetramethyl ammonium iodide, and the hydriodides of ammonia, methylamine, dimethylamine, and trimethylamine, are obtained. From the first of these five compounds trimethylamine can be obtained by converting it into the hydroxide by the action of moist silver oxide and distilling the hydroxide. The tetramethyl ammonium iodide is easily separated from the mixture by distilling with caustic potash, when it remains behind unchanged. The four bases all distil over, and are condensed in a receiver cooled by a freezing mixture, a part of the ammonia and methylamine escaping. To the liquid mixture ethyl oxalate is added:

Methylamine forms $\begin{array}{l} CONHCH_3 \\ | \\ CONHCH_3 \end{array}$ Dimethyl oxamide.

Dimethylamine forms $\begin{array}{l} CON(CH_3)_2 \\ | \\ COOC_2H_5 \end{array}$ Ethyl dimethyl oxamate.

} Separated by the action of cold water, which dissolves the ethyl dimethyl oxamate. On hydrolysis they yield the amines.

Trimethylamine is unacted on, and may be distilled off. *See also under* Betaine, Choline, Narcotine, *and* Neurine.

Trimethylene (*Chem.*) (1) The compound trimethylene $H_2C \overset{CH_2}{\triangle} CH_2$ is a gas; burns with a bright flame. With bromine it yields trimethylene bromide, and with hydriodic acid normal propyl iodide. It is obtained from trimethylene bromide by boiling with sodium. It would be better called cyclopropane. From it are derived a series of homologues and carboxylic acids. The carboxylic acids can be obtained in several ways, *e.g.* (i) by the action of ethylene dibromide on ethyl disodiummalonate:

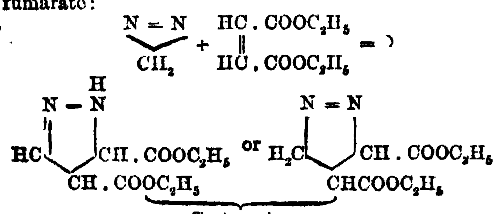
$$\begin{array}{l} CH_2Br \\ | \\ CH_2Br \end{array} + Na_2C\begin{array}{l} \diagup COOC_2H_5 \\ \diagdown COOC_2H_5 \end{array} =$$

$$\begin{array}{l} H_2C \\ | \\ H_2C \end{array} \rangle C\begin{array}{l} \diagup COOC_2H_5 \\ \diagdown COOC_2H_5 \end{array} + 2NaBr$$

On hydrolysing, and heating the resulting acid, trimethylene monocarboxylic acid is obtained:

$$\begin{array}{l} H_2C \\ | \\ H_2C \end{array} \rangle C\begin{array}{l} \diagup COOH \\ \diagdown COOH \end{array} = \begin{array}{l} H_2C \\ | \\ H_2C \end{array} \rangle CH . COOH$$

(ii) By the action of diazomethane (*q.v.*) on ethyl fumarate:



Tautomeric.
Diethyl — 4 : 5 pyrazolinedicarboxylate.

$$= H_2C \begin{array}{l} \diagup CH . COOC_2H_5 \\ | \\ \diagdown CH . COOC_2H_5 \end{array} + N_2$$

Cf. under Pyrazole. The 1 : 2 trimethylene dicarboxylic acids are known in the cis-and trans-forms. *See* Stereoisomerism. (2) The group—$CH_2 . CH_2 . CH_2$— is called trimethylene; it only occurs in combination, as for example in trimethylene bromide—

$$CH_2Br . CH_2 . CH_2Br,$$

and in glutaric acid (*q.v.*) Trimethylene Bromide is a colourless liquid; boils at 165°. With sodium it yields trimethylene (*q.v.*); with potassium cyanide it yields the nitrile of glutaric acid (trimethylene cyanide). It is prepared from allyl bromide (from allyl alcohol, amorphous phosphorus, and bromine) by the saturating it at about − 20° with hydrogen bromide and allowing the liquid to stand in sealed tubes at 30° for twenty-four hours, and repeating the process as long as allyl bromide can take up the gas:

$$\begin{array}{l} CH_2 \\ \| \\ CH \\ | \\ CH_2Br \end{array} + HBr = \begin{array}{l} CH_2Br \\ | \\ CH_2 \\ | \\ CH_2Br \end{array}$$

Trimmer (*Carp. and Join.*) A short joist running across an opening, and serving to support the ends of a number of other joists which have been shortened in order to form the opening. *See* Floors.

Trimmer Arch (*Build.*) The arch supporting the front hearth of an upper floor.

Trimmer Joists (*Carp. and Join.*) The joists supporting the ends of a trimmer (*q.v.*). Sometimes termed Trimming Joists.

Trimming (*Bind.*) Taking a shaving off the rough edge of the leaves of a book that is not to be cut down.

—— (*Carp. and Join.*) Supporting the cut ends of joists by means of a Trimmer (*q.v.*)

Trindle (*Bind.*) A thin flat implement of wood or metal in the shape of an elongated U; used in pairs for making the back of a book in boards assume a flat position previous to placing in the press for the operation of cutting the foredge. *See* Bookbinding.

Trinitrophenol (*Chem.*) *See* Picric Acid.

Trio (*Music*). (1) A musical composition for three voices or instruments. (2) The term given to the secondary movement of a march, minuet, etc. *See also* Repeat.

Triolein (*Chem.*) $\begin{array}{l} CH_2OOC_{17}H_{33} \\ | \\ CH.OOC_{17}H_{33} \\ | \\ CH_2.OOC_{17}H_{33} \end{array}$ (Glyceryl trioleate).

An oil; melts at − 6°; is oxidised on exposure to air, becoming acid; nitrous acid changes it to an isomer elaidin. For occurrence *see* Oleic Acid. It can be prepared from olive oil by allowing the oil to stand with occasional shaking over caustic soda solution for twenty-four hours; the soaps formed by hydrolysis of the other glycerides are dissolved in dilute alcohol when triolein remains. *See also* Iodine Absorption.

Trional (*Chem.*) $\begin{array}{l} CH_3 \\ C_2H_5 \end{array} \rangle C(SO_2C_2H_5)_2$ (Diethylsulphone methylethylmethane). White crystalline powder; melts at 76°; sparingly soluble in water, readily soluble in alcohol and ether. It is used as a hypnotic. Prepared from methylethyl ketone just as sulphonal (*q.v.*) is prepared from dimethyl ketone (acetone).

Trioses (*Chem.*) Sugars containing three carbon atoms. There are two of them:

Aldo-triose. Glycerine aldehyde. Glycerose.	Keto-triose. Glycerine ketone. Dioxyacetone.
CH_2OH	CH_2OH
$CHOH$	CO
CHO	CH_2OH

The aldose should exist in dextro-, lævo-, and inactive forms, but only the inactive form is known. A mixture of the two trioses is obtained by the oxidation of glycerine by means of bromine in presence of a weak alkali, such as lead hydroxide or sodium carbonate. The aldose can be obtained by boiling acrolein dibromide with much water and removing the hydrobromic acid by silver oxide: it is a crystalline solid which melts at 138°; reduces Fehling's solution; condenses on standing with a dilute alkali to β-acrose; yields an osazone (*q.v.*) The ketone can be obtained by the fermentation of a 5 or 6 per cent. solution of glycerine in broth by the sorbose bacterium (B xylinum) in 30 per cent. yield; also synthetically from symmetrical dibromacetone by the action of alkalis: it is a crystalline solid; no constant melting point; reduces Fehling's solution; alkali acts as on the aldose; yields an osazone.

Tripalmitin (*Chem.*) $\begin{array}{l} CH_2 . OOC . C_{15}H_{31} \\ | \\ CH \;. OOC . C_{15}H_{31} \\ | \\ CH_2 . OOC . C_{15}H_{31} \end{array}$ (Glyceryl tripalmitate).

A crystalline solid; melts at 50°, then solidifies, and melts again at 66°; nearly insoluble in alcohol; very soluble in ether; it occurs in many fats and especially in palm oil; it can be made from glycerine and palmitic acid. *See* Palmitic Acid.

Trip Gear (*Eng.*) The arrangement of levers and catches used for opening and closing the valves of Corliss engines, etc.

Triphenylcarbinol (*Chem.*) $HO-C{\left\langle\begin{array}{l} C_6H_5 \\ C_6H_5 \\ C_6H_5 \end{array}\right.}$

Crystallises in plates; melts at 159°; boils above 360°; soluble in benzene, alcohol, and glacial acetic acid. The solution in the latter solvent is turned yellow by addition of hydrochloric acid; the substance also dissolves in concentrated sulphuric acid with the same strong yellow colour—the colour is probably due to the same cause as that of a solution of triphenylmethyl in ionising solvents. *See* Triphenylmethyl. Its paratriamido derivative is the colour base of Pararosaniline (*q.v.*) When dissolved in acetyl chloride, it gives a violet colour, which passes into dark red, and finally yields triphenylchlormethane, but no acetate:

$(C_6H_5)_3C . OH + CH_3COCl = (C_6H_5)_3C . Cl + CH_3COOH.$

Triphenylcarbinol can be obtained in several ways: (1) from pararosaniline (*q.v.*); (2) from triphenylmethane (*q.v.*); (3) from benzophenone and magnesium phenylbromide. *See* Magnesium Compounds.

$$C{\left\langle\begin{array}{l} C_6H_5 \\ O \\ C_6H_5 \end{array}\right.} + Mg{\left\langle\begin{array}{l} C_6H_5 \\ Br \end{array}\right.} = C{\left\langle\begin{array}{l} C_6H_5 \\ C_6H_5 \\ OMgBr \\ C_6H_5 \end{array}\right.}$$

$$C{\left\langle\begin{array}{l} C_6H_5 \\ C_6H_5 \\ OMgBr \\ C_6H_5 \end{array}\right.} + H_2O = C{\left\langle\begin{array}{l} C_6H_5 \\ C_6H_5 \\ OH \\ C_6H_5 \end{array}\right.} + Mg{\left\langle\begin{array}{l} OH \\ Br \end{array}\right.}$$

(4) From triphenylchlormethane by solution in strong sulphuric acid and cautious addition of water. Yield 99 per cent.

$$Ph_3C . Cl + H_2SO_4 = HCl + Ph_3C . OSO_3H$$
$$Ph_3CO . SO_3H + H_2O = Ph_3C . OH + H_2SO_4$$

$(Ph = C_6H_5)$

Triphenylchlormethane (*Chem.*) $Cl-C{\left\langle\begin{array}{l} C_6H_5 \\ C_6H_5 \\ C_6H_5 \end{array}\right.}$

A white crystalline solid; melts at 108°—112°; soluble in benzene, carbon disulphide, and chloroform, sparingly soluble in ether. When heated over 250° it gives diphenylenephenylmethane $\left.\begin{array}{l} C_6H_4 \\ | \\ C_6H_4 \end{array}\right\rangle CH . C_6H_5$

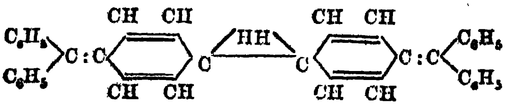
Its benzene solution, when allowed to stand in contact with certain metals such as zinc, silver, mercury, gives triphenylmethyl (*q.v.*) For the action of strong sulphuric acid *see* Triphenylcarbinol. *See also* Triphenylmethane. When heated with silver acetate it yields an acetate which melts at 37°. It is best prepared by condensing carbon tetrachloride with benzene by means of aluminium chloride. The two former, pure and dry, are placed in a flask with reflux condenser, and the aluminium chloride (from chlorine and aluminium) is added in portions of 10 grams at a time (CCl_4 1 part : C_6H_6 3·5 parts : $AlCl_3$ 1·25 parts). Then the mixture is heated for an hour on a water bath. The cooled product is poured in a thin stream on much powdered ice, and benzene is added from time to time, with constant stirring to keep the triphenylchlormethane in solution. The benzene is separated and washed with diluted hydrochloric acid, then water—the washings must be done quickly. The solution is dried over calcium chloride, then concentrated as far as possible on a water bath—over half separates in pure crystals, which may be filtered off and washed with dry ether. More can be obtained by working up the mother liquor.

Triphenylmethane (*Chem.*) $H-C{\left\langle\begin{array}{l} C_6H_5 \\ C_6H_5 \\ C_6H_5 \end{array}\right.}$

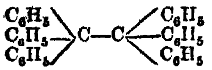
Colourless prisms or leaves; melts at 93°; boils above 300°; very soluble in benzene, ether, chloroform, less soluble in alcohol. On oxidation with chromic acid it gives triphenylcarbinol (*q.v.*) For its conversion into pararosaniline *see* Pararosaniline. Its paratriamido derivative is the leuco compound of pararosaniline. Triphenylmethane is best prepared from triphenylchlormethane (*q.v.*)—15 grams of this in powder are added to 60 cc. glacial acetic acid (in which it is little soluble); 15 grams of zinc powder are added, and carbon dioxide is passed through the liquid, which is kept efficiently stirred by a turbine for several hours at the ordinary temperature. The mixture is then gently warmed, filtered, and the zinc washed with warm glacial acetic acid. Water is added little by little to the filtrate, when the triphenylmethane crystallises out in good but slightly yellow crystals. It is washed with water, and recrystallised from benzene and alcohol. From benzene it crystallises with benzene of crystallisation. Yield of not recrystallised product 92 per cent.

Triphenylmethyl (*Chem.*) $C_{38}H_{30}$. The following formulæ have been successively suggested for this compound, which was discovered by Gomberg:

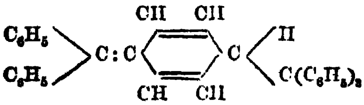
$\left.\begin{array}{l} C_6H_5 \\ C_6H_5 \\ C_6H_5 \end{array}\right\rangle C$ Gomberg's formula (trivalent carbon atom).



Heintschel's formula
(suggested to avoid a trivalent carbon atom).



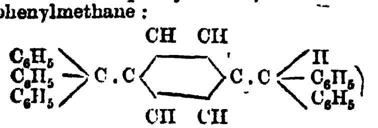
Tschitschibabin's formula
(hexaphenylethane).



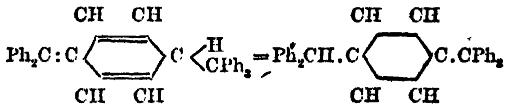
Jacobson's formula.

1-diphenylmethylene-4-triphenylmethyl-cyclohexadien (2, 5).

It is necessary to point out here that the compound called hexaphenylethane by Gomberg is a compound so called by Ullmann and Borsum, its discoverers; but Tschitschibabin has shown that in all probability it is not hexaphenylethane, but benzhydryltetraphenylmethane :



because it reacts quantitatively with only one molecular proportion of bromine, when exposed to sunlight and in carbon disulphide solution, forming a monobromide which readily hydrolyses to a carbinol. For this reason Tschitschibabin suggested the hexaphenylethane formula for Gomberg's triphenylmethyl, and the formula last written for benzhydryl-tetraphenylmethane. This compound will be referred to in what follows as hexaphenylethane U.B. Triphenylmethyl is a colourless crystalline solid, but turns yellow on keeping; it melts (out of air) at 145° to 147°, first blackening and turning red after melting; it distils at 208° under a pressure of 19 mm. mercury, but with decomposition, much triphenylmethane being formed. Its molecular weight was determined by the lowering of the freezing point of each of the following solvents—benzene, naphthalene, nitrobenzene, dimethylaniline, parabromtoluene, phenol—in an atmosphere of carefully purified atmospheric nitrogen; the mean of twelve experiments was 477, while $(C_6H_5)_3C$ requires 243. Gomberg inclines to the view that the result is due to molecular association. Its electric conductivity in liquid sulphur dioxide is comparable to that of many salts; thus its molecular conductivity increases from 8·24 at a dilution of 24 litres to 39·6 at a dilution of 2138 litres. It is very soluble in chloroform and carbon disulphide; pretty soluble in carbon tetrachloride and toluene. From toluene it crystallises beautifully, but the crystals contain toluene. It is also soluble in ethyl acetate and ether; the crystals formed from these solvents are compounds $(C_6H_5)_3C \cdot CH_3COOC_2H_5$ and $\{(C_6H_5)_3C\}_2(C_2H_5)O$. Non-ionising solvents yield colourless solutions; ionising solvents yield yellow solutions (halochromic, *i.e.* the production of colour without the presence of any colour producing radical or grouping). This yellow colour is ascribed by Gomberg to the presence of the ion $(C_6H_5)_3C$—. In its reactions triphenylmethyl behaves as a strongly unsaturated compound; thus it unites, as stated before, with several of its solvents—it absorbs oxygen with great avidity when a solution of it is exposed to air or oxygen, forming a white crystalline peroxide—1·5 grs. of the hydrocarbon in benzene solution absorbed 60 cc. oxygen in the first minute of its exposure. $C_{38}H_{30}+O_2=C_{38}H_{30}O_2$, it unites directly with chlorine, bromine, and iodine, but in the case of the two former, substitution as well as addition occurs. Hydrogen chloride in benzene solution changes it to hexaphenylethane U.B.

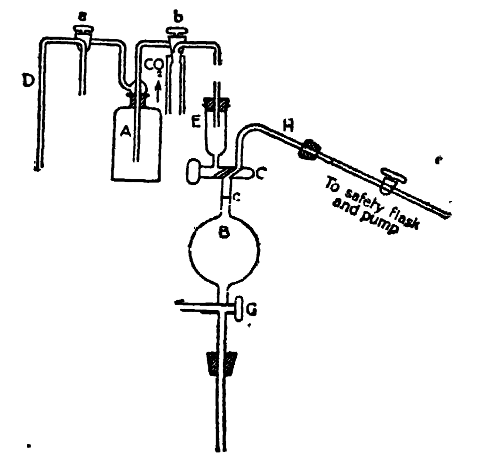


$(Ph=C_6H_5)$

Triphenyl methyl is prepared by reducing a dry benzene solution of triphenylchlormethane with fine zinc shavings. The solution (20 grs. in 100 cc.) is put in the Drechsel washing bottle A, 10 grams of the zinc is added, and the bottle held on its side so that the zinc is spread on the walls; all air is removed by a quick stream of dry carbon dioxide, and the taps *a* and *b* are shut. After a few hours the zinc has sintered together; the bottle is then stood upright and left for five to ten days. The reactions are

$$2Ph_3C \cdot Cl + Zn = C_{38}H_{30} + ZnCl_2$$
$$Ph_3C \cdot Cl + ZnCl_2 = Ph_3C \cdot ClZnCl_2.$$

A is now connected to B, and B is exhausted and



NOTE.—G is a three-way cock, like *a* and *b*. The tube in A goes nearly to the bottom of the bottle.

filled with dry carbon dioxide, these operations being repeated several times. The cocks *b* and C are now turned so that the liquid is drawn from A to B, and the double salt remaining in A is washed with benzene drawn through D into A, then into B. A is now removed, the benzene distilled off under reduced pressure, while B is partly surrounded by rubber tubing, through which steam is blown. B is detached from receiver, and 50 cc. acetone run into B from E, and violently shaken to break up lumps of triphenylmethyl; B is filled with carbon dioxide and apparatus left till cool. Then a suction flask is put on to the rubber stopper below G, and the acetone is sucked off, leaving the crystals in B; the treatment is

repeated with cold acetone. Finally, B is exhausted and filled with carbon dioxide alternately till the product is perfectly dried; it is got out by cutting the tube at *c* and blowing carbon dioxide through. Triphenylmethyl so obtained is very pure, and can even be exposed to air for a while without change. Gomberg has prepared several analogous compounds to this—but not yet in pure condition. Two of the most remarkable are the paratolyl and paranitrophenyl compounds. The former changes spontaneously into the hexaparatolylethane U.B., and it does not take up iodine; its solution is orange inclining to red. The nitro compound gives a remarkable colour display during its formation (molecular silver was used instead of zinc).

Triple Counterpoint (*Music*). Three-part counterpoint written in such a way that all the parts are invertible, each serving as lower, middle, and upper part.

Triple Expansion Engine (*Eng.*) An engine in which the steam is expanded in three cylinders in succession. *See* STEAM ENGINE.

Triple Point (*Heat*). A point on the vapour pressure curve of a substance, at which the substance can exist simultaneously in the solid, liquid, and gaseous states. It is the point of intersection of the curves showing the relation between the pressure and temperature of the solid and vapour, liquid and vapour, and solid and liquid. *See also* VAPOUR PRESSURE *and* SUBLIMATION.

Triplet (*Music*). A group of three notes to be performed in the time of two.

CHOPIN.

It is generally marked by a slur and the figure 3, and may consist of notes, or notes and rests.

Triplet Cycle. *See* TANDEM.

Triple Time (*Music*). *See* TIME *and* TIME SIGNATURE.

Trip Lever (*Eng.*) A bent lever used in trip gear (*q.v.*) One end of the lever is raised by means of a cam; when the cam has passed a certain point, the lever is released and falls suddenly.

Tripod (*Photo.*) A three legged stand for a camera, used in out of door photography where a firm but portable support is required.

Triste (*Music*). Sad.

Tristearin (*Chem.*) *See* STEARIN.

Tristezza, Con (*Music*). With sadness.

Tritone (*Music*). Three tones. Another name for the interval of the Augmented Fourth. It occurs between the Subdominant and Leading Note.

Tritriglyph (*Architect.*) An arrangement of the Doric frieze and intercolumniation such that three triglyphs are used between those immediately above two adjacent columns. *See* TRIGLYPH; ARCHITECTURE, ORDERS OF; ENTABLATURE; MONOTRIGLYPH; *and* DITRIGLYPH.

Triturate (*Chem.*) Grinding substances together so as to facilitate solution or reaction.

Trivalent Element *or* **Radical** (*Chem.*) *See* VALENCY.

Trivet (*Textiles*). *See* TRUVAT.

Trochilus (*Architect.*) *See* SCOTIA.

Trolley *or* **Trolly** (*Elect. Eng.*) A metal wheel or roller attached to the end of a flexible TROLLEY POLE (*q.v.*) on the top of an electric tram or car. The trolley is placed in contact with an electric conductor, in the form of a wire, which extends along the track, supported by standards. The current is conveyed by the trolley to the motor circuit on the car.

—— (*Eng., etc.*) A low built truck or car, generally used for moving heavy materials.

—— (*Lace Manufac.*) A form of lace in which the pattern is outlined with a thickened thread or by a narrow flat border. The ground is generally double with meshes of different shape.

Trolley Pole (*Elect. Eng.*) A pole fixed on the top of an electric car and carrying a conducting wire, which is connected with the motor circuit on the car. To the upper and flexible end of the pole is attached the Trolley (*q.v.*)

Tromba (*Music*). (1) Trumpet (*q.v.*) (2) A reed stop of 8 ft. pitch on Organs. *See p.* 441.

Trombone (*Music*). (1) A brass instrument. *See* MUSICAL INSTRUMENTS, *p.* 437. (2) A powerful organ reed stop of 8 ft., 16 ft. or 32 ft. tone. *See p.* 441.

Trona (*Chem.*) A naturally occurring compound of sodium with carbonic acid having the formula $Na_2CO_3 2NaHCO_3 . 3H_2O$. It is obtained artificially by boiling a solution of sodium bicarbonate for a short time only. On cooling the salt crystallises out.

—— (*Min.*) A hydrous sodium carbonate and bicarbonate composition; soda = 37·8, carbonic acid = 40·2, water = 22 per cent. Mono-symmetric. Grey or yellowish. From Mexico and near Fezzan, in Africa, in both of which localities it is worked commercially.

Tropæolins (*Chem.*) Azo dye stuffs. The chief are:

TROPÆOLIN D, $\begin{array}{l} N \overset{(1)}{—} C_6H_4SO_2ONa(4) \\ \| \\ N \overset{(1)}{—} C_6H_4N(CH_3)_2(4) \end{array}$, is the sodium salt of dimethylamidoazobenzeneparasulphonic acid. It is commonly called METHYL ORANGE (*q.v.*), or Helianthine, and is used as an indicator. *See* INDICATORS.

TROPÆOLIN OO, $\begin{array}{l} N \overset{(1)}{—} C_6H_4SO_2ONa(4) \\ \| \\ N \overset{(1)}{—} C_6H_4NHC_6H_5(4) \end{array}$, also called ORANGE IV., Fast Yellow, etc., is an orange yellow crystalline solid obtained by diazotising sulphanilic acid and acting on the product with an acid-alcoholic solution of diphenylamine. It is a valuable orange yellow dye for wool and silk.

TROPÆOLIN G is the same as the last compound

except that the sulphonic acid group occurs in the meta-position, and it dies a yellower shade.

TROPÆOLIN O, $\begin{array}{l} N \overset{(1)}{-} C_6H_4SO_2ONa(4) \\ \| \\ N \overset{(1)}{-} C_6H_3 \langle {OH(2) \atop OH(4)} \end{array}$ also called RESORCIN YELLOW, is a yellowish brown solid. The free acid is nearly black, and has a green lustre. It is obtained by diazotising sulphanilic acid, and acting on the product with resorcin (*q.v.*) It dies wool and silk a golden yellow.

TROPÆOLIN OOO No. 1, $\begin{array}{l} N^{(1)}C_6H_4SO_2ONa(4) \\ \| \\ N^{(1)}C_{10}H_6OH(4) \end{array}$ (ORANGE I. *or* NAPHTHOL ORANGE), is a reddish brown powder. The free acid resembles the preceding. It is obtained by diazotising sulphanilic acid and acting on the product with α-naphthol. It dyes wool and silk orange.

TROPÆOLIN OOO No 2 (ORANGE II.) is a bright orange colour. The free acid crystallises out the same colour, but is red when anhydrous. It is obtained in the same way as the preceding compound except that β-naphthol is used instead of α-napthol (*see* NAPHTHOLS), so that the hydroxyl occurs at (2) in the naphthalene ring. It is a very important orange dye, and dyes a brighter colour than ORANGE I.; further it is not acted on by alkalis.

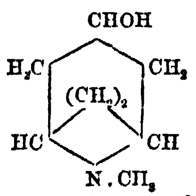
Tropical Year (*Astron.*) The period from one vernal equinox to the next; it is nearly equal to 365¼ mean solar days (*q.v.*) *See also* YEAR.

Tropic of Cancer (*Astron.*) The northern of the two circles on the celestial sphere whose distance from the equator is 27° 27′ 30″. equal to the obliquity of the ecliptic. This northern circle touches the ecliptic at the sign *Cancer*, hence the name. The sun's annual path is by these two circles. *See also* TROPICS.

Tropic of Capricorn (*Astron.*) The southern of the two circles referred to under TROPIC OF CANCER. It touches the ecliptic at the sign *Capricorn*, hence the name. *See also* TROPICS.

Tropics (*Astron.*) Strictly speaking, the two parallels of latitude 27° 27′ 30″ N. and S. of the Earth's Equator. In ordinary usage the word is applied to the whole region lying between these two parallels of latitude: the region is more correctly termed the Torrid Zone. These N. and S. parallels are termed the Tropic of Cancer and of Capricorn respectively.

Tropine (*Chem.*)



A white crystalline solid (plates); melts at 63°; boils at 229°; soluble in water and in alcohol, less soluble in ether. It contains two asymmetric carbon atoms (those adjacent to nitrogen in the ring), but it is not known in an active form, probably owing to a form of internal compensation. It exists in the cis- and trans- forms (*see* STEREOISOMERISM), the second form being known as ψ-tropine. Tropine and ψ-tropine can be converted into each other by oxidising them both to tropinone, the corresponding ketone. This ketone on reduction with sodium and alcohol gives ψ-tropine, and on reduction with zinc dust and hydroiodic acid yields tropine. ψ-tropine melts at 108° and boils at 240°. The tropines are tertiary bases and secondary alcohols. Their acid esters are called tropeines. The formula for tropine shows that it contains: (1) A pyridine ring; this is shown by the fact that ethyl pyridine can be prepared from it. (2) A pyrrole ring; this is shown by the fact that tropinic acid (*see* PYRROLE) can be prepared from it. (3) A seven carbon atom ring; this is shown by the fact that an unsaturated ring hydrocarbon tropilidene, which is cycloheptatriene,

$$\begin{array}{l} CH_2 - CH = CH \\ \qquad\qquad\quad | \\ \qquad\qquad\quad CH, \\ \qquad\qquad\quad \| \\ CH = CH - CH \end{array}$$

can be prepared from it, and further tropine has been synthesised from this hydrocarbon. The importance of the Tropines lies in the fact that a number of important alkaloids are closely related to them. *See* ATROPINE, COCAINE, and HYOSCYAMINE. Tropine is prepared by the hydrolysis of atropine or hyoscyamine.

Troppo (*Music*). Too much, as Allegro ma non troppo—Cheerfully, but not too much so.

Trough. A term of wide application, but usually signifying an open shallow vessel.

—— (*Build.*) A rain water gutter under the eaves of a roof.

—— (*Met.*) The CONVERTING POT or fireclay box in which bars of iron are placed for conversion into steel by the cementation process (*q.v.*)

Trousse (*Archæol.*) A case holding a number of small utensils, hung from the girdle, and worn during the middle ages. *Cf.* ETUI.

Trowel. A tool consisting of a thin blade of iron or steel, triangular, oval, or oblong in shape, with a raised handle. Used by bricklayers and masons for spreading and dressing mortar, etc.; by plasterers for finishing off plaster work; and by moulders for smoothing and shaping the sand or loam forming a mould. A gardener's trowel is scoop shaped.

Trowelled Work (*Plast.*) Plastering that is finished with a trowel instead of with a plasterer's float.

Troy. *See* WEIGHTS AND MEASURES.

Trs. (*Typog.*) *See* TRANSPOSE.

Truck. (1) A low built vehicle, tray, platform, etc., running on wheels. (2) A group of two or more pairs of wheels in a frame, used to support one end of a railway carriage or locomotive. *See* BOGIE TRUCK *and under* RAILWAYS.

—— (*Lace Manufac.*) An antifriction roller or bowl; used in conjunction with a "cam," or what is known in weaving as a tappet (*q.v.*)

Trumpet, Tromba (*Music*). (1) A brass instrument. *See* MUSICAL INSTRUMENTS, *p.* 436. (2) A reed stop on organs. *See p.* 441.

Truncated. Cut short; the term is applied commonly to a cone or pyramid the vertex of which has been cut off.

Trundle (*Music*). A roller used in the drawstop action in the organ. *See* MUSICAL INSTRUMENTS, *p.* 439.

Trunk Engine (*Eng.*) An old form of engine in which the piston rod was a hollow tube, termed a TRUNK, passing through stuffing boxes in both ends of the cylinder. The connecting rod was hinged to a pin fixed inside the trunk.

Trunk Hose (*Cost.*) A garment something like a bag in shape covering the person from the waist to the middle of the thigh or the knee, where it was gathered in. Worn during the sixteenth and seventeenth centuries, generally in conjunction with the jerkin.

Trunk Piston *or* **Plunger** (*Eng.*) A piston or plunger in the form of a tube, with the connecting rod hinged to a gudgeon pin inside it. *See* GAS ENGINE, PETROL ENGINE, *etc.*

Trunnion (*Eng.*) The short projecting axle or pivot on which an oscillating cylinder, a heavy gun, Bessemer converter, etc., turns.

Truss (*Eng., Build, etc.*) A framed structure used to support a roof, etc. *See* ROOFS.

Trussed Shaft (*Eng.*) A long shaft which is stiffened by a series of parallel rods, arranged on an imaginary tube-like surface round the shaft, and fixed to it at their ends. As the shaft revolves, the rods which are at any instant in the lowest position are brought into tension, and resist the tendency of the shaft to bend.

Trussing (*Eng.*) Stiffening any structure by means of rods serving as ties and struts.

Truth (*Eng., Build., etc.*) This word is used in many trades to denote accuracy, symmetry, etc.

Truvat *or* **Trivet.** A small instrument fitted with a sharp steel blade used for cutting the loops of hand woven velvet and other Terry fabrics, so as to form pile (*q.v.*) *See also* VELVET.

Try Cocks (*Eng.*) Two small cocks fitted to a boiler, one being above, the other below, the normal water line. They afford a means of ascertaining (approximately) the level of the water if the gauge glass fail to act.

Trying Plane (*Carp. and Join.*) The form of plane used for finishing surfaces that have to be true and straight. *See* PLANES.

Trying Up (*Carp., etc.*) A term equivalent to "trueing up"; shaping a piece of wood so that its surfaces are accurately plane, and its angles are right angles.

Trypsin (*Zoology*). A proteolytic ferment found in the pancreatic juice. It differs from pepsin (*q.v.*) in acting in an alkaline medium.

Try Square (*Eng., etc.*) A SQUARE (*q.v.*) used for testing the accuracy of right angles on a piece of work. It consists generally of a steel blade set in and at right angles to a stock.

T-Slots *or* **Tee Slots** (*Eng.*) Grooves in the table of a planing machine, etc., whose cross section is in the form of an inverted T: the heads of the bolts used for holding down pieces of work on the table are passed into these slots.

T-Square *or* **Tee Square.** A SQUARE (*q.v.*) used chiefly by draughtsmen; it is made of wood, usually pear or mahogany, and has a thin blade, sometimes tapering on one side, and varying in length from 1 to 3 ft., according to the size of drawing board with which it is to be used.

Tuba (*Music*). (1) A reed stop on organs of 8 ft. pitch and heavy wind pressure; also called *tuba mirabilis* and *tuba major.* (2) A brass instrument of the bombardon species. *See* MUSICAL INSTRUMENTS, *p.* 438.

Tube (*Eng., etc.*) A general name for pipe of any description, excepting that made of cast iron.

Tube Cleaner (*Eng.*) A scraper or a brush, on the end of a long thin rod, used for clearing out the tubes of a boiler.

Tube Cutter. A tool by means of which tubing can be cut. The most usual form consists of a curved holder which grips the tube, and a sharp edged circular cutting wheel, which is pressed against the tube and moved gradually round it, making a cut in the metal as it travels.

Tube Drawing (*Eng., etc.*) The process of making tubing by drawing it through a steel plate furnished with holes of suitable size. The closing up of the joint may be effected in this process, or the joint may be brazed or welded previously. Solid drawn tubes are produced either by forcing the metal through an orifice, a mandrel or "triblet" being fixed concentrically so as to produce the bore of the pipe, or else by taking a short, thick cast tube, and elongating it by the process of drawing.

Tube Expander (*Eng.*) A tool used for widening the ends of metal tubing by means of pressure applied to the inside of the tube. Used especially in fixing the ends of boiler or surface condenser tubes in the tube plate (*q.v.*) The holes in the latter are bored out to fit the tube; the end of the former is placed in the hole, and then expanded sufficiently to cause the plate to grip the end of the tube firmly and so hold it in position.

Tube of Force (*Elect.*) Consider an area on which there is a charge of electricity; let lines of force (*q.v.*) be drawn from every point in the boundary of this area; they will form a tubular surface, which is known as a Tube of Force. If the area contain a unit charge, the tube is termed a Unit Tube. The end of a tube of force is an area containing a charge equal in amount but opposite in sign to that on which the tube commenced.

Tube Plate (*Eng.*) The plate which carries the ends of the tubes of a boiler or surface condenser.

Tube Vice *or* **Pipe Vice.** A clamp fixed to the bench, etc., used for holding pieces of tube while being cut or screwed.

Tube Wrench. A form of wrench (*q.v.*) with serrated jaws capable of gripping a piece of pipe firmly, in order to screw it up into a socket, etc.

Tubing (*Eng., etc.*) A term applied in engineering chiefly to pipes of other material than cast iron—*e.g.* wrought iron, steel, brass, copper. It is distinguished as "solid drawn" when made without a seam; if made with a seam, the joint is brazed, welded, soldered, or in some few cases riveted.

Tub Sizing (*Paper Manufac.*) The process of sizing paper, after it has been made, with gelatine.

Tubular Boiler (*Eng.*) A general term for a boiler having a number of tubes. *See* BOILERS.

Tubular Compass (*Surveying*). A compass needle mounted in a tube, and so arranged that it can be read by looking through the tube, as in a telescope, instead of over the needle as usual.

Tubular Compasses. Compasses whose legs are formed of two (or more) pieces, one sliding inside another in the manner of a telescope, so that they can be lengthened at will.

Tubular Girder (*Eng.*) A hollow girder, whose cross section may be either rectangular (Box Girder) or curved.

Tucker (*Cost.*) A piece of linen, lace, muslin, or other light fabric shaped or arranged to cover the neck and shoulders; worn especially during the seventeenth and eighteenth centuries.

Tucking In *or* **Under** (*Foundry*). Ramming the sand underneath the lowest parts of a pattern during moulding.

Tudor (*Architect.*) *See* PERPENDICULAR.

Tudor Flower (*Architect.*) An ornament resembling the fleur-de-lys, used as a cresting in Perpendicular Gothic work.

Tudor Rose (*Architect.*) *See* ROSE.

Tue Iron (*Eng., etc.*) A TUYERE (*q.v.*)

Tuff *or* **Tufa** (*Geol.*) A term originally applied to pumice stone or a similar light porous lava; it is now used of rocks composed of somewhat fine fragments (such as the dust, ashes, and stones from a volcano) which have become more or less consolidated. *See also* AGGLOMERATE.

Tula Work. *See* NIELLO.

Tulip Woods. *See* WOODS.

Tumbler. (1) A kind of spring latch forming part of a lock. It detains the bolt until the key lifts it and sets the bolt free. (2) One of a set of levers from which the heddles (*q.v.*) are suspended in certain forms of loom.

—— (*Leather Manufac.*) A term applied to a drum in which leather is tumbled to soften or retan it.

Tumbler Bearing (*Eng.*) A form of bearing used to support the long shaft which drives a travelling crane. It is movable, and is displaced as the mechanism of the crane passes it, afterwards returning to its original position.

Tumbler Lock. A lock furnished with a set of discs or latches which must undergo some arrangement with regard to each other before the bolt can be moved.

Tumbler Tank (*Plumb.*) A flushing tank fitted with an oblong receiving vessel which is divided by a central cross partition. The receiver is pivoted and fitted in such a manner that when a quantity of water has run into one of the two compartments it tilts and discharges its contents, bringing the other compartment into position to be filled when the operation is repeated.

Tumbling Bay (*Civil Eng., etc.*) A form of weir, used in estimating the quantity of water which passes over itself in any given time. If the water flows over a horizontal edge of breadth b and the depth of water over the edge $= h$, then the total in cubic feet passing over per second is $C\,b\,h^{\frac{3}{2}}$ where C is a constant which may be found by experiment. If the water pass through a V shaped notch, and h be the depth of water above the lowest point of the V, then $Q = Ch^{\frac{5}{2}}$ where C is again a constant determined by experiment.

Tumulus (*Archæol.*) A prehistoric burial mound.

Tungstates (*Chem.*) *See* TUNGSTEN.

Tungsten (*Chem.*) W. Atomic weight 180. (Also called Wolfram.) A rather rare metal belonging to Group VI., Series 10, of the Periodic System. It is steel grey in colour; has a very high unknown melting point (far above that of platinum); specific gravity about 19; oxidised in air only at a red heat; slowly attacked by water containing carbonic acid; aqua regia oxidises it to the trioxide; when finely divided it is dissolved by boiling caustic potash, forming a potassium tungstate and liberating hydrogen. Tungsten occurs as Scheelite (*q.v.*) and as Wolfram (*q.v.*) $\{CaWO_4$ and $2FeWO_4.3MnWO_4\}$ and in some rarer minerals. The metal is obtained from the trioxide by mixing it with sugar charcoal (800 WO_3 : 80C) and heating the mixture for ten minutes in the electric furnace (900 amp. and 50 volts). Tungsten alloys with iron to form tungsten steel, which is very hard and retains magnetism better than ordinary steel. TUNGSTEN TRIOXIDE, WO_3, is a yellow powder; becomes orange when heated; turns greenish on exposure to light (reduction?); insoluble in water and acids; reduced by heating in hydrogen, first to a blue oxide of uncertain formula, next—at dull redness—to the dioxide WO_2, a red brown powder, and at higher temperature still to the metal. It dissolves on warming with solutions of alkaline hydroxides or carbonates forming tungstates. It is prepared from Wolfram by prolonged digestion with hydrochloric acid to extract the iron and manganese—the acid is renewed from time to time and at last a little nitric is also added; from the residue tungstic acid is extracted by ammonia, forming ammonium tungstate, which is crystallised and finally heated when the trioxide remains. Tungsten trioxide is called by mineralogists tungstic acid. CHLORIDES: The hexachloride WCl_6 forms dark violet crystals; melts at 275°; boils at 347°; it is obtained by heating the metal in excess of chlorine in absence of air and moisture. The pentachloride WCl_5 is obtained by distilling the hexachloride two or three times in a current of hydrogen; it melts at 248°; boils at 276°; forms black needles or a green powder. The tetrachloride WCl_4 is a deliquescent grey brown crystalline powder, decomposed by heating into the pentachloride and dichloride; it is obtained by distilling a mixture of the two former chlorides in a current of carbon dioxide. The dichloride WCl_2 is a grey powder obtained by heating the tetrachloride in a current of carbon dioxide. Two oxychlorides, $WOCl_4$ and WO_2Cl_2, are known. TUNGSTIC ACIDS and TUNGSTATES: Tungsten trioxide combines with water in many different proportions to form tungstic acids; it also unites with acid oxides and water to form complex acids such as silicotungstic acids, phosphotungstic acids. Orthotungstic acid, H_2WO_4, is a yellow solid practically insoluble in water and acids, and obtained by boiling the trioxide in caustic soda to form a tungstate, which is then decomposed by boiling with hydrochloric acid. Metatungstic acid is $H_2W_4O_{13}7H_2O$. Paratungstates are derived from the unknown acids $H_6W_7O_{24}$ and $H_{10}W_{12}O_{41}$; many tungstates derived from other acids than these are known. Only a few compounds which find application are described below. SODIUM PARATUNGSTATE, $Na_{10}W_{12}O_{41}28H_2O$, is the ordinary commercial sodium tungstate; it forms white efflorescent crystals and is used to make cotton and linen uninflammable; it is obtained as

a by product in the extraction of tin (*q.v.*) from its ores when these contain tungsten, and it is also made by fusing wolfram with sodium carbonate, extracting the melt with water and crystallising. The tungsten bronzes are obtained by reducing sodium tungstates in various ways, as by heating in hydrogen, or with tin, or iron, or by electrolysis; they have metallic lustre, are insoluble in acids and alkalis, soluble in sodium hypochlorite, and with ammonia and silver nitrate they give silver and tungsten trioxide, but those rich in the trioxide require heating with these reagents in sealed tubes. A blue bronze, $Na_2W_5O_{15}$, is obtained by melting sodium paratungstate and electrolysing with six Grove's cells; it is a good conductor of electricity; the purple red bronze, $Na_2W_3O_9$, is best obtained by melting together 12·6 parts of sodium carbonate and 68·9 parts of tungsten trioxide for about half an hour and extracting the product successively with water, caustic soda, and hydrochloric acid. Potassium only forms one bronze. PHOSPHOTUNGSTIC ACIDS: The various tungstic acids unite with orthophosphoric acid to form a series of complex acids; the existence of acids formed by the union of 12, 16, 20, and 24 molecules of tungsten trioxide with one molecule of phosphorus pentoxide seems to be certainly established. Phosphoduodecitungstic acid ($H_3PW_{12}O_{40}$ + 25 to 30 H_2O) is obtained by dissolving sodium paratungstate (500 grs.) and ordinary sodium phosphate (250 grs.) in water (500 c.c.), boiling, and adding concentrated hydrochloric acid (750 c.c.); the liquid is evaporated to crystallising point, allowed to cool, and shaken with ether. The lowest layer is separated, the ether driven off, and crystallised. It forms nearly colourless efflorescent crystals; soluble in water. It is used as a precipitant for alkaloids, proteids, urea, ptomaines (putrescine and cadaverine especially), and many of the splitting products of proteids such as the diamino-acids and phenylalanine.

Tungstic Ochre (*Min.*) Also called Tungstite and Wolframine. An oxide of tungsten, WO_3; tungsten = 79·3, oxygen = 20·7 per cent. It is of a light yellow colour, usually pulverulent, and occurring as a coating in Wolfram or Scheelite as a result of their decomposition, hence its localities are those of these two minerals.

Tungstite (*Min.*) *See* TUNGSTIC OCHRE.

Tunic (*Cost.*) A garment shaped something like a shirt and worn either inside or outside other garments. The tunic was commonly worn by the Romans of either sex; that of the Roman senator was distinguished by having a broad vertical purple stripe (*latus clavis*) over the breast.

Tuning Fork (*Sound, Music*). A U shaped fork, usually of tempered steel, having a stem projecting from the base of the U which serves as a handle. On being set in vibration (by striking, bowing, etc.) a nearly pure musical tone is emitted; as the pitch of this tone varies only slightly with temperature, a tuning fork is very useful as a standard of pitch, and for many scientific purpose. For musical purposes forks are most commonly tuned to A or C. *See* PITCH (*Music*).

Tunnel (*Civil Eng.*) An underground passage excavated horizontally (or nearly so) in order to accommodate a railway, road, canal, etc. The wall and roof are supported by arched masonry (except in certain cases when the rock can stand alone without support); this masonry, termed the LINING, is usually continued under the floor of the tunnel, forming a complete tubular arch. Drainage is effected by side channels on the floor, or by a culvert running below the formation level; ventilation is effected in long tunnels by shafts, or if these are impracticable (as in the St. Gothard Tunnel) by fans.

Tunnel (*Marine Eng.*) The hollow passage between the engine room and the sternpost, through which the propeller shaft of a steamship runs.

—— (*Mining*). *See* ADIT.

Tunnel Bearings (*Eng.*) Those bearings of a propeller shaft which are placed within the tunnel (*q.v.*)

Tup (*Eng.*) (1) The main mass of iron forming the head of a steam hammer; it carries a steel block on its lower side which forms the actual face of the hammer. (2) A ram.

Turban (*Cost.*) The distinctive headdress worn by men in Moslem countries. It consists of a shawl or scarf, varying in colour, wound round a tarboosh.

Turbine (*Eng.*) A turbine is a motor in which "rotary motion is obtained by the gradual change of momentum of a fluid" (Neilson). It consists typically of a set of fixed vanes or blades, termed GUIDE BLADES, which direct the motion of the fluid so that it impinges upon another set of vanes carried by a revolving axle, the whole mechanism being contained in a casing of suitable form. Turbines may be classified, according to the direction of flow of the fluid, as (1) RADIAL FLOW TURBINES, in which the fluid diverges from the axis (OUTWARD FLOW), or converges to it (INWARD FLOW), and (2) AXIAL FLOW TURBINES, in which the motion of the fluid is parallel to the axis. A third type, or MIXED FLOW TURBINES, includes machines in which a combination of these forms is used.

WATER TURBINES.—These are most commonly radial flow machines, though for a small head of water (*e.g.* less than 30 feet) a parallel flow turbine, such as those of Fontaine and Jonval, is very suitable. The efficiency of these is about 70 per cent. Outward flow turbines are said to be unsteady in action, but their efficiency is higher than the preceding, sometimes attaining 88 per cent. One of the best known forms is that invented by Fourneyron. Inward flow turbines have been designed by Swain, J. Thompson, and others, and have an efficiency in the best examples of nearly 90 per cent.

When the head of water exceeds 100 feet, a different type, the IMPULSE TURBINE, is advisable. In this form the passages are not full of water, as in the ordinary turbine, but the water rushes with high velocity through a series of jets or nozzles and impinges on suitably shaped blades. The Girard turbine has been successfully used under a head of 650 feet. The PELTON WHEEL has vanes formed into pairs of cups or pockets, the jet impinging on the edge separating two cups and dividing into two parts. A Pelton wheel is used at the Comstock mine in Nevada, with a head of over 2,000 feet, the peripheral velocity of the wheel being 180 feet per second. The efficiency may reach 80 to 85 per cent. under favourable circumstances.

STEAM TURBINE.—The steam turbine, though the most modern form of the steam engine in practice, is the most ancient in actual history, the germ of the invention dating from Hero of Alexandria, in the second century B.C. No further invention is recorded until the engine of Branca (1629), in which a jet of steam impinged on a wheel with vanes—a device which is the parent of the modern engine of De Laval. Other inventions are due to Kempeln (1784), Watt

(1784), Sadler (1791), Trevethick (1815), Ericsson (1830), and Perkins (1836); but the steam turbine in practical work begins at the time when the Hon. C. A. Parsons, F.R.S., carried out successful experiments in 1884. An engine of 10 h.p. made at this time to drive a dynamo was in actual work for some years, and is now to be seen in the Museum at South Kensington. This is a parallel flow turbine, having a series of wheels carrying the blades, all being mounted on one shaft, the sets of guide blades projecting inward from the case. The steam passes from one wheel to the next in succession. By the year 1888 a number of parallel flow turbines, all being non-condensing, were in use for driving dynamos, the total horse-power amounting to about 4,000. In 1889 a temporary reversion to the radial flow type was made for reasons associated with the patent situation; in 1892 condensers were added, thereby for the first time rendering turbines comparable with piston engines with respect to steam consumption, and a number of large turbines were built for electric lighting stations at Cambridge, Newcastle, Scarborough, and London.

The most modern steam turbines adopt the method of parallel flow, which has advantages over the radial flow type in simplicity of construction. The general arrangement of the blades in the Parsons turbine is shown in Fig. 1, the moving blades being light, the fixed or guide blades dark.

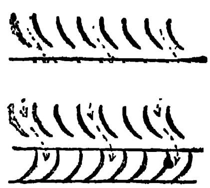


Fig. 1.

Of a different type is the turbine of De Laval, mentioned above. The steam emerges from a series of nozzles and strikes against vanes mounted at the periphery of a single disc (Fig. 2), which revolves at an enormous velocity—*e.g.* 30,000 revolutions per minute in a small engine. The shaft carrying the turbine wheel is flexible, and carries specially designed gear wheels by which the speed is reduced to a suitable amount. De Laval's work was undertaken at just about the same time as Parsons'; and while the De Laval turbine is not built in large sizes, a number of features, notably the diverging nozzle, have been employed in other types, and have had a most important influence on steam turbine development. Other forms of turbine are being rapidly introduced, one of the best known being the Curtis turbine, in which the steam approaches the first ring of blades through inclined nozzles, and afterwards passes through a series of fixed and moving blades alternately. The Curtis turbine has been developed to the widest extent in accordance with vertical shaft designs, with the condenser immediately below the turbine, and constituting an integral part of the machine.

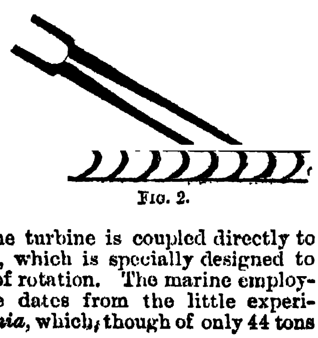

Fig. 2.

The chief applications of the steam turbine up to the present have been to the driving of dynamos and to the propulsion of vessels. In the former case the shaft of the turbine is coupled directly to that of the dynamo, which is specially designed to suit the high speed of rotation. The marine employment of the turbine dates from the little experimental vessel *Turbinia*, which, though of only 44 tons displacement, attained a speed of 34¼ knots. Turbine engines have since been fitted to vessels of larger and larger dimensions, up to ocean liners and battleships, with extremely promising results. Turbine engines have also been applied in various other ways, *e.g.* to the driving of fans and blowers.

Many experiments have been made with a view to applying the principle of internal combustion, as used in gas and oil engines, to the turbine. No practical success has yet been attained, but it is by no means impossible that the difficulties may ultimately be overcome.

Turibulum. A thurible (*q.v.*)

Turkey Red. *See* Dyes and Dyeing.

Turkey Umber (*Dec.*) This name is given to one of the finest qualities of umber because, although mined in Cyprus, it was formerly taken to Constantinople for export. Turkey umber resembles the umbers generally in composition, being chiefly composed of the hydrated oxides of iron and manganese. The fact that the umbers contain considerably more of the latter oxide than the ochres do is the reason of the separation of the two classes, ochres being yellow and umbers brown. Turkey umber has a particularly warm violet brown colour, for which it is highly valued. Its nearest equivalent is probably the Irish umber known as Cappagh brown. It is found that the addition of a little lamp-black to many of the second rate umbers makes them something like Turkey umber, and this adulteration is therefore practised, and has to be guarded against. Like the umbers generally, Turkey, or as it is sometimes called, Cyprus umber, can have various shades imparted to it, in place of its natural colour, by heat. The intensity and duration of the heat are varied according to the result desired; but while the natural warmth of the colour can be enhanced by moderate heat, it is irretrievably lost on overheating.

Turmeric. This consists of the roots of at least two species of plants—*Curcuma longa*, an East Indian plant belonging to the ginger family, and *Canna speciosa*, a West African shrub. In this country, however, all the turmeric is of East Indian origin. The roots come on the market either as "bulbs" or "fingers." The roots are brownish yellow outside and yellow within. The fingers are from 20 to 32 in. long, and the bulbs are sometimes 18 or even 20 in. in diameter, and either spherical or egg shaped. The roots yield on distillation an ethereal oil having a spicy taste and smell. They are sold as such or in powder. In the latter case they are often adulterated with ochre and other mineral yellows, which, however, are at once detected by their great weight when the powder is stirred up in water, or by the amount of ash left on burning a sample. This will not exceed 5 per cent. with genuine turmeric. Turmeric is still to a small extent employed in dyeing textiles, in spite of its looseness both to light and washing. What small amount of use it still finds in this direction is due to the fact that it is a direct dye for wool, silk, cotton, and all other fibres, going on quite as well without a mordant as with one, and that the yellow is very bright. Turmeric can be used to shade faster colours, by which it is afterwards to some extent protected. Like the dye woods, it is used in the form of decoction, but it is wasteful, as the colouring matter known as curcumine is only sparingly soluble, even in boiling water. Turmeric also supplies the chemist with a test paper second in value to litmus paper only. Coarsely powdered

turmeric root is digested in strong spirits of wine for a few days in a warm place. The spirit dissolves out the whole of the curcumine, and assumes a deep orange yellow colour. Blotting paper is soaked in the tincture, and then dried and cut up. The resulting slips are unaffected by acid liquids, but assume a deep chocolate brown when dipped into alkalis. What is still more important, they behave to boric acid as if it were an alkali, and if a solution turns blue litmus paper red and yellow turmeric paper brown, the presence in it of boric acid is practically certain. One illegitimate use of turmeric is to colour mustard which has had its colour diluted by adulteration with starch. The characteristic behaviour of turmeric to alkalis which do not alter the colour of genuine mustard at once betrays the fraud. When powdered turmeric is adulterated with starch, as sometimes happens, a microscopic examination will at once reveal the fact to any one acquainted with the microscopic appearance of starch granules. Again, a very weak solution of iodine in solution of potassium iodide has no effect upon genuine turmeric, but turns a sample adulterated with starch blue immediately.—A. S. J.

Turn (*Music*). *See* ORNAMENTS (*Music*).

—— *or* **Turns** (*Eng., etc.*) *See* TURNS.

Turnbull's Blue (*Chem.*) $Fe''.Fe'''_2\{Fe(CN)_6\}_2$ (Ferrousferric ferrocyanide). A blue solid with a coppery lustre: the air-dried product contains about 28 per cent. of water; insoluble in water and in dilute acids; on heating it gives Prussian blue and ferric oxide; boiled with potash it gives hydrated ferrosoferric oxide and potassium ferrocyanide:

$$Fe''Fe'''_2\{Fe(CN)_6\}_2 + 8KOH = 2K_4Fe(CN)_6 + \{Fe(OH)_2 + Fe_2(OH)_6\}$$

It forms a constituent of commercial Prussian blue. It is obtained by precipitating potassium ferrocyanide with a mixture of ferrous and ferric sulphate, also by adding potassium ferricyanide to an excess of a ferrous salt such as ferrous sulphate—in this case the ferricyanide oxidises a part of the ferrous salt to the ferric salt, and is thereby reduced to ferrocyanide when the reaction becomes the same as before.

—— (*Dec.*) Turnbull's blue was discovered by Gmelin, but it is named after a colour maker who prepared it as his own invention. Turnbull's blue is a pigment suitable for use either as a water or as an iron colour. Its colour, a violet blue, that of Prussian blue having a greenish shade, is not very bright, and is far from permanent, as it turns brown gradually, like Prussian blue, on exposure to the air. It is also expensive to make, as red prussiate of potash from which it has to be made is much dearer than the yellow prussiate. Hence, Turnbull's blue is now rarely used.

Turned Sorts (*Typog.*) When a work or job requires the very frequent use of a particular letter or "sort" it often happens that the stock is prematurely used up, and as a temporary expedient the compositor turns a letter of the same thickness with the foot of the shank upwards and the face downwards, which turned sort is easy to be seen, and is afterwards rectified.

Turner (*Eng., etc.*) A workman employed at the lathe.

Turner Jenny (*Cotton Spinning.*) *See* DOUBLING.

Turnery. (1) The shop in which the lathes are situated. (2) A trade term for various wooden articles produced by turning (*q.v.*)

Turning (*Eng., etc.*) The shaping of work in the lathe. Such work is usually cylindrical in section, but not always so—for example, plane surfaces, whose profile is not necessarily circular, can be produced by the operation of SURFACING (*q.v.*) Turned work varies greatly in nature and in size, from the smallest pivots used in a watch to immense pieces of ordnance or the turntables (*q.v.*) used for railway work. The accuracy obtainable in turning exceeds that which is attained by any other machine tools.

Turning Bar (*Build.*) A CHIMNEY BAR (*q.v.*).

Turning Chisel. A chisel whose cutting edge is oblique, *i.e.* not at right angles to the length or main axis of the tool; used in turning the softer woods in the lathe.

Turning Gouge. A gouge used in roughing out most soft wood when turning, as well as in finishing off concave portions of the work. The profile or outline of the cutting edge is usually rounded off, *i.e.* it forms an arc of a circle, whose radius varies with the size of the gouge.

Turning Moment *or* **Torque.** The MOMENT of a COUPLE (*q.v.*) which acts on a body and produces a tendency to turn. *See also* MOMENT OF A FORCE.

Turning On (*Silk Manufac.*) *See* BEAMING.

Turning Over (*Moulding*). The method of moulding in which each half of the mould is rammed up separately as distinguished from BEDDING IN, in which the lower half of the mould is fixed, the sand being pressed round the pattern from above.

Turnings (*Eng.*) The shavings and fragments removed during turning.

Turning Saw (*Carp. and Join.*) A narrow bladed saw adapted for cutting along a curved line. The name is sometimes applied to a Bow Saw or a Compass Saw (*q.v. under* SAWS).

Turning Tools. For soft wood turning the chief tools are the Turning Gouge and Chisel (*q.v.*) For hard woods other forms of chisel and gouge are used, as well as tools resembling those used for turning the softer metals, such as brass. Metal turning tools are made with stronger blades or shanks, and with cutting edges at an obtuse angle. The actual profile of the cutting edge varies greatly; in the GRAVER and DIAMOND POINT it is triangular or pointed; in ROUND NOSE tools it is rounded; in SIDE TOOLS the cutting edge is on the side, and parallel to the length of the tool; PARTING TOOLS, used for cutting through a piece of metal in the lathe, are very narrow. SLIDE REST TOOLS vary greatly in the form of the cutting edge, but are forged with a square shank by which they are held in the slide rest.

Turning Up (*Bind.*) The process of making the back of a book in boards assume a flat position for the purpose of cutting the foredge; effected by means of trindles. *See* TRINDLE *and* BOOKBINDING.

Turnpin (*Plumb.*) A cone shaped piece of hard wood, used for opening the ends of lead pipes.

Turns *or* **Turn.** An old name for a lathe; still applied to a watchmaker's lathe, which is a small dead centre lathe.

—— (*Music*). *See* ORNAMENTS, *p.* 478.

Turnscrew. A SCREWDRIVER (*q.v.*)

—— (*Typog.*) A small flat piece of steel usually oval in form used for fastening or unfastening the slide screw of a composing stick.

Turnsole (*Botany*). A red dye formed by fermentation of the leaves of *Chrozophora tinctoria* (order, *Euphorbiaceæ*), a native of Grand Gallargues in the south of France; has been used for centuries in the cheese industry in Holland.

Turntable (*Eng.*) A circular revolving platform on which a locomotive, etc., can be placed in order that it may be reversed, or shifted from one line of rails to another. The table has a central pivot, and is also supported at its circumference by wheels or rollers running on a circular ring.

Turn Up (*Plumb.*) The part of a lead or zinc gutter turned up so as to rest against the wall.

Turpentine (*Dec.*) The word "turpentine" is used in two senses. It may either mean the crude exudation of certain coniferous trees or the more volatile products of the distillation of these exudations. The latter is more properly called oil or essence of turpentine, and it is proposed in this article to deal with crude turpentine and oil of turpentine separately.

Crude Turpentine.—Almost all *Coniferæ* yield this product, but only a few of them yield it in sufficient quantities for commercial exploitation. The chief varieties of crude turpentine, each with its conifer of origin, are as follows:

Name.	Tree of Origin.	Remarks.
	A. COMMON TURPENTINE.	
American	*Pinus palustris* or *australis*, the long leaf or yellow pine	Thickly flowing. Yields up to 17 per cent. of oil of turpentine.
French	*Pinus pinaster* or *maritima*	More fluid than American. Yields up to 25 per cent. of oil.
German	*Pinus sylvestris* " *rotundata* " *nigra* *Picea vulgaris*	Semi-fluid, tough and sticky with an unpleasant smell. Completely soluble in alcohol. Yields up to 30 per of oil.
	B. RARER TURPENTINES.	
Venice	*Larix decidua*	Milky when first drawn but clears soon afterwards. It is colourless or brownish, bitter and with a not unpleasant smell. Dries slowly. Yields from 18 to 28 per cent. of oil.
Hungarian	*Pinus pumilio* or *nigricans*	Clear. Pale yellow and thin and with a hot aromatic smell and taste.
Carpathian = Cedar Balsam	*Pinus cembra*	Thin, colourless, and smelling like juniper. Taste bitter and spicy.
Strassburg	*Abies alba* or *pectinata*	Very thin, yellow or brown, and dries easily. Very bitter and with a lemon-like smell. Not wholly soluble in alcohol. Yields about 25 per cent. of oil.
Canada Balsam	*Abies canadensis* or *balsamea*	Thin, pale yellow, with a pleasant smell and sharp aromatic taste. Dries rather slowly.
Cyprus or Chian Turpentine	*Pistacia terebinthina* and *P. vera*	Clear or slightly turbid, and of a greenish yellow colour. The taste is spicy, and the smell resembles that of fennel. It is fully soluble in ether.

Turpentine is obtained by cutting into the wood through the bark. The resin which then exudes is collected either in a cavity scooped out in the tree itself or in a pot or other vessel fixed to the tree in such a position that the liquid will flow into it. The collection of the turpentine generally takes place all through the summer, but spring is the harvest time in North America. The exact method of cutting the trees varies greatly. In many places the cuts are made on either side of an imaginary line drawn vertically on the trunk and inclined towards the line so that the exudations from all the cuts will meet and pass to a common receiver. It is of great importance, however, that the turpentine should be frequently collected and, if not at once distilled, put into receptacles where it is shielded from the air. Exposure to the air gradually hardens and coagulates the turpentine, and as this hardening takes place solely from the resinification of the oil, it means loss of the most valuable constituent of the raw product.

The period during which a tree can be tapped varies considerably, and depends a good deal upon the age of the tree when the tapping was commenced. It probably averages about twenty years. In France, where the exploitation of turpentine is very scientifically carried out, the trees are first tapped when about twenty-five years old, and are usually exhausted in twenty years, although there are instances of much more prolonged vitality. In America the state of affairs is practically the same. The annual yield of a tree may be put as averaging 15 to 16 lb. per annum.

OIL OF TURPENTINE.—This is prepared by distilling crude turpentine with water until no further distillate passes over. In the condensers the oil floats on the top of the water, and is therefore easily separated from it. The residue in the still is resin or colophony, which is either used in this form or is separated into resin oils and pitch by another distillation at higher temperatures.

Oil of turpentine is mainly a mixture of various terpenes, and varies in its nature according to the tree from which the crude turpentine was obtained. The terpenes are polymers of C_5H_8, some having the

formula $C_{10}H_{16}$ and some $C_{15}H_{24}$. Their chemical constitution is practically unknown, but they are numerous, and no two oils of turpentine agree in the terpenes they contain, although in most cases this difference does not affect the practical employment of the oil. The following are some particulars about the turpentine oils most largely used:

American.—This has an average specific gravity of from ·86 to ·87. It is nearly always dextrorotatory, but in some cases it is slightly lævorotatory. It boils at about 158° C., and almost the whole (90 per cent. at least) should distil below 165°.

French.—Practically the only difference between this and the American oil is that the French product is invariably lævorotatory.

German.—This is again dextrorotatory, with about the same gravity, but a somewhat higher boiling point than the American oil.

Russian.—Russian oil of turpentine is the heaviest of all, having a specific gravity approaching 0·875 or even 0·88. It is dextrorotatory, and boils between 170° and 175° C. Its disagreeable and persistent smell is a great bar to its use. Were it not for this its cheapness would secure for it a far larger consumption.

The chief use of oil of turpentine is for thinning oil varnishes. It is impossible to thin them with oil, as the time of drying would thereby be unduly lengthened. Turpentine oil thins the varnishes till they can be easily applied with a brush without precipitating them, and as it is volatile the diluted varnish dries as quickly as the undiluted. Turpentine oil is also used to some extent in medicine in the treatment of bronchitis, and as an anthelmintic, as well as externally as a rubefacient. The pharmaceutical terebenum is prepared by the treatment of rectified oil of turpentine with sulphuric acid. The acid destroys the optical activity of the oil, whether it is dextro or lævorotatory, and is then removed by repeated washing with water.

The chief adulterants of oil of turpentine are petroleum and resin oil. Both are easily detected on distillation. If the oil does not begin to boil below 155° C., and leaves practically no residue after prolonged exposure to a temperature of 165°, it may be considered pure. Oil of turpentine is itself employed as an adulterant of many essential oils. It may be mentioned, in conclusion, that the separation of oil of turpentine from the natural resin exuding from pine trees is an operation at least 1,200 years old. It is mentioned by Marcus Græcus in the eighth century in a work entitled *Liber ignium ad comburendos hostes.* This may be rendered "A work on fires for burning up your enemies."—A. S. J.

Turpeth Mineral (*Chem.*) A basic sulphate of mercury formed by boiling mercuric sulphate (*see* MERCURY COMPOUNDS) with water; it is a yellow powder sparingly soluble in water.

Turquoise (*Min.*) A hydrous phosphate of aluminium with a low variable percentage of cuprous oxide. Usually reniform or encrusting. Colour, the blue of the same name. From India, Thibet, Arabia, Persia, etc. It is used extensively as a precious stone. *See* PRECIOUS STONES.

Turret (*Architect.*) A small tower. A turret containing a stair is frequently attached to the main tower of a church.

—— *or* **Capstan** (*Eng.*) A form of rotating tool holder carried on a slide rest. A number of tools are fixed in the holder, and any one of these can be brought into action at will, thus enabling a number of operations to be carried out in succession on the same piece of work. The use of a turret greatly facilitates the production of repetition work.

Turret Lathe. A lathe fitted with a TURRET *or* CAPSTAN (*q.v.*).

Turwahr Bark (*Leather Manufac.*) This is the bark of a species of acacia (*Acacia auriculata*) used in India for tanning sheepskins.

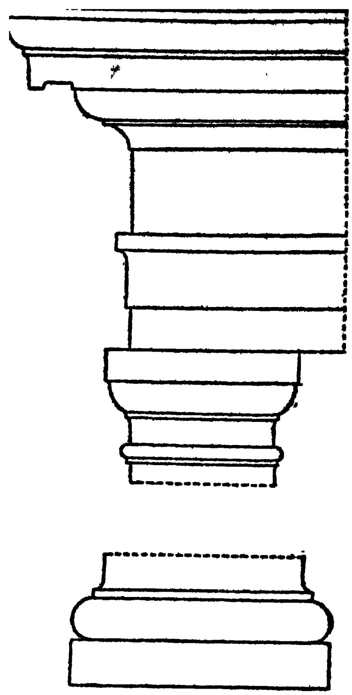
Tuscan Order. A modification of the Doric order used by the Romans. *See* DORIC *and* ARCHITECTURE, ORDERS OF.

Tusk Tenon (*Carp. and Join.*) A form of tenon used in large framing, having the form shown in Fig. 5, p 754 (*art.* TENON).

Tutti (*Music*). All; full.

Tuyere *or* **Twyere** (*Eng., Met., etc.*) The nozzle or jet through which an air blast enters a furnace or fire. The name is also spelled TUER, TWEER, *and* TUE IRON.

Twaddell Degrees. *See* HYDROMETER.



TUSCAN ORDER.

Twaddell's Scale. *See* HYDROMETERS.

Tweezers (*Typog.*) Small pincers of spring steel with fine pointed jaws used for extracting a type from a line or page of matter.

Twelfth (*Music*). (1) An organ stop sounding the interval of a twelfth above the note played. (2) The interval of the double fifth.

Twelvemo *or* **Duodecimo** (*Print., etc.*) A sheet of paper folded so as to form 12 leaves (24 pages); generally written 12mo. A book made up of sheets folded in this manner. *Cf.* OCTAVO, QUARTO, SIXTEENMO.

Twentyfourmo (*Print., etc.*) A sheet of paper folded so as to form 24 leaves (48 pages); generally written 24mo. A book (of small size) made up of sheets folded in this manner. *Cf.* OCTAVO, QUARTO, TWELVEMO.

Twilight (*Astron.*) The illumination of the upper air after the sun has set. It continues so long as any portion of this illuminated air remains in sight of the observer. Caused by reflection of sunlight from upper portion of the earth's atmosphere.

Twill (*Textile Manufac.*) A simple type of weave, resulting in a fabric with fine lines or ribs traversing the cloth diagonally from selvedge to selvedge. Broad classification is that of warp and weft twills, in which the warp and weft respectively make the face of the cloth.

Twin Crystals (*Min.*) Crystals, the two halves of of which show a rotation from the normal of 180° in a plane known as the twin plane (*q.v.*) Sometimes the crystals appear to penetrate one another; they are then known as Interpenetration Twins.

Twinkling of Stars (*Astron.*) *See* SCINTILLATION.

Twin Plane (*Min.*) An imaginary plane in a twinned crystal which is either parallel to a possible face or normal to a possible zone axis, of each of the members of the twin system, and is such that if one half of the twin system were revolved in that plane through two right angles, it would occupy the place of the other half. *See* SYSTEMS OF CRYSTALS.

Twin Screws (*Eng.*) A pair of screw propellers, one being placed on each side of the sternpost of a steamship. They are right and left handed, and are rotated in opposite directions when the vessel is steaming straight ahead.

Twist. Turning, convolution, or flexure. The term is also used loosely to include torsional stresses and strains.

—— (*Textiles*). *See* YARN.

Twist Bits (*Carp. and Join.*) Bits having a thread and cutters at the end, and twisted in their length. *Cf.* TWIST DRILL.

Twist Cop (*Cotton Spinning*). *See* COP.

Twist Drill (*Eng.*) A drill having a cylindrical body or shaft with two (or more) grooves of helical or screw shape running round it. It is the best form of drill for almost any purposes. The end of the drill is accurately ground to a conical shape, and the cutting edges are formed by the intersection of this conical surface with the grooves.

Twist Drill Grinder (*Eng.*) A machine in which a twist drill is held and pressed against a revolving emery wheel, in order to produce a truly conical point whose axis coincides with that of the shaft or body of the drill.

Twister (*Textile Manufac.*) A machine on which fancy yarns are obtained by folding two or more threads together.

Twist Hand (*Lace Manufac.*) A workman employed in any description of twist lace; a lace maker.

Twisting (*Silk Manufac.*) The process of joining a new warp to the thrum (*q.v.*) in the loom, the threads being played out one by one on the cross rods and joined with a twist by finger and thumb. *Cf.* TWISTING IN.

Twisting In (*Weaving*). An alternative process to drawing in. Attaching the threads of a new warp to the ends of a finished warp which have been previously drawn through the healds or harness mails.

Twisting Moment. TORQUE *or* TURNING MOMENT (*q.v.*)

Twist Lace (*Lace Manufac.*) Lace made upon what is usually known as Nottingham lace machinery, after Heathcote and Lever's principles, in which bobbins and carriages are employed. *See* LACE MANUFACTURE.

Two High Mill *or* **Rolls** (*Met.*) A rolling mill consisting of two rolls, one above another. *See* ROLLS.

Two Line Letters (*Typog.*) Letters of the depth of two lines of type and used as initials. *See* TYPES.

Two Salt Water. Water in which the amount of dissolved salt is double that of normal sea water. This is the highest degree of concentration which the water in a marine boiler should be allowed to reach.

Two Throw Crank (*Eng.*) A shaft with two cranks forged or fixed upon it, the cranks usually being at 90° with each other.

Two Tone (*Lace Manufac.*) A term appplied to lace composed of cotton of the natural colour (ecru) interspersed with objects of white.

Twyere *or* **Tuyere** (*Eng., Met., etc.*) *See* TUYERE.

Tympan (*Print.*) A thin iron frame covered with parchment on which the sheet of paper to be printed is placed. *See* TYPOGRAPHY.

Tympan Hooks (*Print.*) Small hooks fixed on the upper side of the outer tympan of a press. *See* TYPOGRAPHY.

Tympani *or* **Timpani** (*Music*). The kettledrum. *See* MUSICAL INSTRUMENTS, *p.* 444.

Tympan Joints (*Print.*) The joints by which the outer tympan is attached to the carriage of a press on which it works. *See* TYPOGRAPHY.

Tympanum (*Architect.*) The space enclosed between the horizontal and raking cornices of a

TYMPANUM.
Essendine Chapel, Rutland.

classical pediment. Similarly, the space between the flat head of a door opening and the arch over.

Tymp Arch (*Met.*) The arch over the opening in the front of the hearth of a blast furnace.

Tynes (*Her.*) The small branches projecting from the antlers of a stag.

Typefounding may be said to date from the time when the early German typographers invented the system of cutting separate punches for each letter or character, and driving the punch into a piece of hard metal, thereby forming the matrix, which was adjusted to one end of a mould, and

types cast therefrom—the body or shank of the type being formed by the mould, and the letter or face by the impression of the punch. Types were originally cast by "hand mould." The operator held the mould with the matrix adjusted in his left hand, and by means of a small ladle poured in a sufficient amount of molten metal to form the type, which was released when the upper and lower sections of the mould were separated.

The art of Typefounding consists of several processes: (1) Designing the face, (2) Cutting the punch, (3) Striking or "growing" the matrix, (4) Justifying the matrix, (5) Mixing the alloy, (6) Casting the type, and (7) Dressing and finishing the product. In designing the face it is necessary that the artist be acquainted with the special requirements of the printing trade and the proportions of each letter in the fount to be produced. The different parts which form the characters must be in strict relation to each other. The cutting of the punch requires patience, artistic skill, and minute attention to details. Steel which has been annealed to allow of easy working is used, and it is afterwards tempered to overcome the resistance of the subsequent driving. The punch may be called a type in steel, the engraved end being tested by minute callipers and gauges to verify the width of the body strokes, the fineness of the cross strokes and the curves and lengths of the ears and serifs, which are subject to certain scales of proportion. A counter punch is sometimes used to form the open space within the letter "O," it being easier to form this hollow by a punch than by the process of engraving. The matrix, which is a small rectangular piece of copper, with one side highly polished, is fixed in a block and the punch driven in by means of a hammer at a point near the top and with equal space at the sides. A small burr in the copper is caused by this operation; this is smoothed off and the impression is mathematically adjusted for the purpose of securing proper alignment and uniform height of all the characters in the fount of type. Matrices are also obtained by a process of electrotyping whereby a large number may be "grown" at one time.

THE PUNCH.

Types are usually cast in an alloy, of which the ingredients are lead, antimony, and tin, the proportions varying according to the size and quality of the letter required. Lead gives ductility to the alloy, antimony the required hardness and sharpness, and tin gives toughness and a finer grain to the mass. Antimony expands in cooling, and thus further assists in the production of a perfect type. A trace of copper is sometimes incorporated. The proportions of a good alloy are: Lead, 48 per cent.; antimony, 25 per cent.; tin, 25 per cent.; copper, 2 per cent.

THE MATRIX.

The hand mould is practically obsolete, but is used occasionally for casting special characters. Similar in principle is the machine mould, which consists of a number of pieces of hardened steel fitted with the utmost mathematical accuracy. It is constructed to open in halves, which separate and release the type when cast. The matrix is fixed in position by a bow spring over the orifice of the mould. Molten metal is injected by means of a pump. As the wheel of the machine revolves, the mould is presented to the nozzle of the pump, receives a charge, and returns with a fully formed type, which is discharged and the operation repeated. An important function of the mould is to form the nicks, which distinguish the many founts of different faces. There may be one or more nicks, and they are caused by fixing into grooves on the front of the mould small pieces of steel wire. Another piece of wire is placed in a drilled hole in the upper body to form the pin mark, which is used for discharging the type after it is cast.

Attached to the body of the type as it leaves the mould is a piece of surplus metal called the "jet," which may be detached automatically at the moment of discharge or be broken off by hand. This is the first necessary process in finishing. The types are then rubbed on the surface of a rough stone to remove any "rag" or burrs arising from an imperfect mould or badly fitted nicks, and afterwards set in lines on narrow wooden sticks. The line is inverted and the break of the jet removed by passing a groove over its whole length. The fronts and backs of the letters are scraped, and the types restored to a face-up position, examined with a lens, and all imperfect letters rejected. In cases where a portion of the face overhangs the body of a type, as in the letters *j* and *y*, kerning is necessary, and this is effected by rubbing the side of the body on which the projection shows along the face of a bevel edge file. By the old hand-casting process a man could produce from 2,000 to 3,000 types in a day. The average machine output is nearer 50,000. Perfecting machines are in use which cast and break off the "jet" of the type, finish, and arrange them in line ready for making up into page. A machine which casts and finishes types still more rapidly is the Wick Rotary Type-casting Machine. This consists primarily of a horizontal wheel with channels on its surface radiating from the centre. In each channel is a sliding piston having a matrix on its end nearest the outer edge of the wheel. The channels are covered with a disc, and thus present a series of openings in the periphery of the wheel corresponding with the size of the types to be cast. As the wheel revolves, these openings pass in succession before a minute opening in the mould through which a constant stream of molten metal is being forced by pumps. When the mould has passed the nozzle, the pistons push out the finished type on to a travelling chain at the rate of about 50,000 an hour.

TYPE WITH JET.

Type High (*Typog.*) The height of a type. The term is used in connection with the mounting of stereo, electro, and engraved plates for use with type.

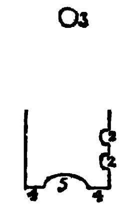
Type Holder (*Bind.*) An implement for holding the metal type when set up for lettering labels or the back and sides of books. *Cf.* HAND LETTERS.

Type Metal (*Chem.*) An alloy of lead, antimony, tin, and occasionally copper. It expands on solidifying. It is used in type founding. Type metals vary a good deal in the proportions of their constituents, *e.g.*:

	I.	II.
Lead . . .	50	82
Antimony . .	25	14·8
Tin . . .	25	3·2

See also TYPEFOUNDING *and* TYPES.

Types (*Typog.*) The letters or characters used in printing. They are generally cast in an alloy of lead, tin, and antimony. In some cases a small percentage of copper is added. They vary in size from the *Minikin* (about 20 lines to the inch) to the large poster series, and the number of faces is infinite. The standards of English founders differ; but the practical base from which all sizes are regulated is the *Pica*—one-sixth part of an inch in depth of body from back to front. The introduction of the Point System has removed many disadvantages arising from lack of uniformity in English bodies. There are 72 points to the inch, and the following table shows the comparative relation of one system to the other in the more important founts:



1. The shank or body.
2. The nicks.
3. The pin mark.
4. The feet.
5. The groove.
6. The front.
7. The back.
8. The shoulder.
9. The bevel.
10. The face.

	Points.	Approximate lines to foot.	Pica Ems.

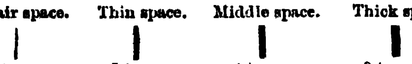
Long Primer	10	86	From the Euphrates, Abraham, not without divine guid
Small Pica	11	78	From the Euphrates, Abraham, not without divine
Pica	12	72	From the Euphrates, Abraham, not without
English	14	62	From the Euphrates, Abraham, not
Great Primer	18	54	

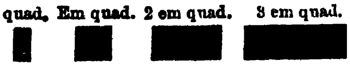
The next sizes in their order are Double Pica, Two line Pica, Two line English, Two line Great Primer, Two line Double Pica, and Canon, which is the last to have a distinctive name. The larger sizes are designated according to the number of picas contained in the depth of body. The *Spaces* and *Quadrats*, used for separating words and filling up blank spaces, are proportionate in thickness to the em of the body:

*Hair space. Thin space. Middle space. Thick space.



8 to em. 5 to em. 4 to em. 3 to em.

En quad. Em quad. 2 em quad. 3 em quad. 4 em quad.



*When founts are cast on the unit set system the types as well as the spaces have the same proportionate relation to the em. The height of a type from the bottom of its feet (4) to the surface (10) is $\frac{9}{10}$ of an inch, or about the diameter of the English shilling.

Type Setting Machines. Those now in use are for the most part improvements on different machines patented by Hattersley, Mackie, and others about the middle of the nineteenth century. Two were in operation in Hull during the year 1862. Ordinary founders' types were used, and the lines were justified by hand. The THORNE machine, which is of this class, composes movable types specially nicked. The types are assembled continuously, and divided into lines of required width by a person who sits near the operator of the machine, which consists of a keyboard and two vertical cylinders. The cylinders are upon the same axis, and are placed one above the other. The surfaces of these cylinders contain a number of channels about an inch deep, running the whole length. The upper cylinder revolves, and has an attachment regulating the distribution of the type. Every channel in this cylinder being filled with lines of mixed type, it is made to revolve, and each type drops as it comes in contact with the groove in the lower cylinder corresponding to the nicks until the various channels are filled. When keys on the board are depressed the corresponding type are transferred from the lower cylinder to a point where they are conveyed by a travelling band to a setting stick and galley for the purpose of being justified. The MONOTYPE machine casts separate types, and assembles and justifies them automatically in successive lines. It is constructed in two parts, *viz.* a keyboard and a casting machine. The keyboard, operated independently, consists of a number of keys corresponding with the characters in the die case of the casting machine, a set of punches, and a registering attachment. As the keys are worked the punches, acted on by compressed air, perforate a roll of paper in special positions, so that when the roll is transferred to the casting machine the perforations regulate the matrices conforming with the letters punched, and bring them into position for casting. At the same time as the perforation is effected, the scale action, previously set to the width of the line required, registers the letters as composed, and towards the end of the line a bell is rung. The operator may then, by depressing keys indicated on the register drum, perforate the necessary spacing for filling out the line. When the roll of perforated paper is transferred to the casting machine it brings the required matrix into position over the mould, through which the metal is pumped. The types are cast in a vertical position, and ejected continuously until a line is completed. It is then drawn off to a galley, the carrier returning to receive successive lines as completed. The LINOTYPE machine, as its name implies, produces a "line-o'-type" instead of separate characters. It consists of three parts in one combination: (*a*) The mechanism for assembling the matrices by the manipulation of the keyboard;

(*b*) the casting apparatus which produces the slug or line from the assembled matrices; and (*c*) the arrangement for distributing the matrices into their respective magazines after the line has been cast. These operations are performed concurrently, *i.e.* the matrices used for the first line are being distributed while those for the second are being cast and those for the third are being composed. The depression of a key releases a matrix from its position in the magazine, which contains all the characters assorted in sloping channels. It is then assembled with others in order of copy until the necessary number of words for a line is completed. The words are separated by space bands consisting of two steel wedges, the outer edges of which are always parallel. The completed line is moved to the elevator and thence to a vice, where the matrices are brought into alignment, and locked against and across the face of the mould. The metal is then forced into the mould, which has already been set to cast the slug in the required length and thickness. It is afterwards mechanically trimmed and delivered to a galley. The discarded matrices are carried by the elevator to the top of the magazine. Over this is fixed a distributor bar with ribs to engage the teeth of the matrices, which slide along until each reaches the mouth of its proper channel. The ribs of the bar being in harmony with the teeth of the matrix, its release is compelled. The MONOLINE machine differs in design and construction from the Linotype. Its output is, however, similar. The machine consists of a keyboard, magazine for matrices, and automatic justifying spacers, a casting well, delivery attachment, and distributing mechanism. The magazine contains 500 matrix bars, each having twelve *intaglio* letters on its front edge. These bars stand behind each other in channels, and are assembled in accordance with the action of the keyboard in lines. The operator moves a lever on the keyboard, and the machine automatically justifies, casts, and delivers the lines on to a galley, and the matrix bars and spaces are returned to the magazine.

Typhoon (*Meteorol.*) Cyclones in the torrid zone in their greatest development are called typhoons or hurricanes. They vary from a few miles to several hundred miles in diameter, and are accompanied by great winds and torrential rain. *See* CYCLONE.

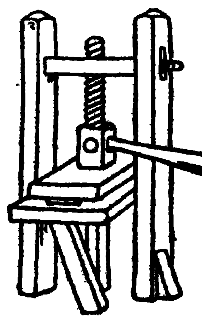
Typography. The art of setting up types and taking impressions from them. The evolution of modern Typography may be traced from the invention of movable types, the secret of which, according to Hadrian Junius, was discovered by Laurent Coster, of Haarlem, and became known to Gutenberg, who in 1439 devoted himself wholly to the art of Typography. Peter Schœffer, working in conjunction with Gutenberg and Fust, invented a method of casting types. These were used in 1454, and the first complete book, the Gutenberg Bible, was issued in 1456. The art was introduced into England in 1476 by William Caxton, who practised it in the precincts of Westminster, using what is known as Black Letter type. Of the notable works produced, *The Dictes and Sayings of the Philosophers* (probably the first book printed in England) and *The Game and Playe of Chesse*, printed in 1474, may be mentioned. Roman types were first used by Wynkyn de Worde, of Lorraine. Later on Typography spread to various towns, notably to Oxford in 1478, and to St. Albans in 1480. Little progress was made in England during the sixteenth century. The first English Bible printed in Roman type was produced in Edinburgh in 1576. On the Continent, Christopher Plantain, of Antwerp, and the Elzevirs, of Leyden, in Holland, had done much to improve the productions of Typography. Printing was established in the North American Colonies during the seventeenth century; but the most famous of its exponents in that part of the world, Benjamin Franklin, was not born until 1706. Previous to 1720, English printers obtained their best types from the Dutch founders, but with the advent of Baskerville and William Caslon a marked advance in English manufacture was begun. To the fine character of the types cast by the latter may be attributed much of the perfection of modern book printing. Caslon commenced casting types for Cambridge in 1750. The early years of the nineteenth century witnessed still further improvement. The eager demand of collectors was the cause of many sumptuous works being produced, almost regardless of cost. About 1830, Charles Whittingham, of the Chiswick Press, by the introduction of headpieces, tailpieces, borders, and other typographical ornaments, effected a revolution in style, and to him and the publisher, William Pickering, is due the inception of "old style" printing. The improvements in the character of types and typographic ornaments, as well as developments in wood engraving, paved the way for the introduction of illustrated periodicals, of which the modern magazine is the outcome. To Mr. Theodore De Vinne, an American printer, may be attributed much of the excellence of modern Typography. He has consistently advocated a high standard of beauty and purity in type faces, and he has also considerably advanced the mechanical processes by introducing the system of printing on dry paper—a necessary condition in the reproduction of photographic process blocks, which have almost entirely superseded wood engravings. Prior to the introduction of type setting machines (*q.v.*), little, if any, change was made in the actual process of *Composing* type. Until about the middle of the nineteenth century the compositor used almost exclusively the same methods and tools as his early predecessors. Any departure was in the direction of "display" or "jobbing work," which the use of complicated ornaments and "fancy" types made possible, and the cultivation of "style" encouraged. Hand composition is accomplished practically on the original plan. The types are "distributed" one by one into shallow cases containing divisions or boxes to hold each character. These cases, which are usually in pairs for ordinary Roman founts, are "put up" on frames in a sloping position. The upper case contains 98 boxes in all, and into these are put the capital letters, small capitals, figures, signs, and "peculiars." The lower case contains 53 boxes of different sizes. For Hebrew, Greek, etc., the divisions of the cases are varied and more complicated. From the cases the types are picked out as required by the compositor, and placed in the "composing stick," a traylike iron frame. By means of this

COMPOSING STICK.

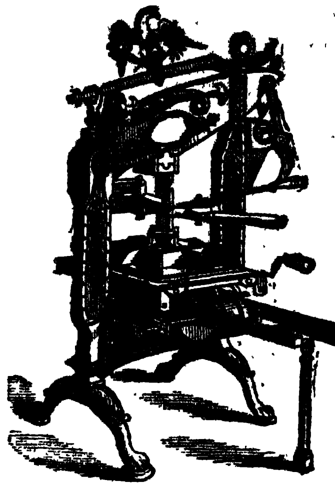
stick the types are arranged in lines, according to "copy." As the stick is filled the matter is lifted on to a galley. "Matter" may be "solid" or "leaded." When the lines of type are close together they are said to be solid, and when opened out, leaded. The leads used

for the purpose are thin strips of metal cut to the full length of the line of type, and of widths varying from $\frac{1}{72}$ to $\frac{1}{24}$ of an inch, the technical terms being 12-to-pica, 8-to-pica, 6-to-pica, and 4-to-pica. The "pica" is one-sixth of an inch. (*See* TYPES.) Leads of a thinner make are sometimes used, and when the strips of metal are thicker than 4-to-pica they are called "clumps." The lines having been spaced and "justified" to equal lengths in the composing stick, they are easily fastened in the galley, and a rough impression obtained on a galley press. This impression, usually termed a "slip" or "first proof," is taken to the reader, whose duty it is to detect and mark all proof corrections (*q.v.*) When the mistakes are corrected, the matter is ready for "making up" (*q.v.*) into pages of the required size. Headlines and folios are added to give the order of pagination. The pages are subsequently "imposed"—that is, laid down upon an iron imposing surface in such order that, when "locked up" and printed on a sheet of paper, the latter may be folded so that the pages follow each other consecutively. The pages are locked up by means of furniture (*q.v.*)—which is arranged in such manner as to give the required margin round the printed pages—and quoins (or wedges) in an iron frame or chase, which in book work usually contains eight, sixteen, or more pages. The combination then becomes a "forme." This imposed forme is now ready for the press. The art of the compositor is not confined to book work. Jobbing and the cultivation of styles of display have opened up large possibilities in the grouping and arrangement of types and lines. Elaborate designs are effected by the use of appropriate ornaments, and the discriminate use of tints and coloured inks in printing materially aid the compositor in producing artistic results. The arrangement of music types, the composition of the Greek and Hebrew languages, tabular matter, and mathematical workings demand no mean degree of mechanical skill and general knowledge.

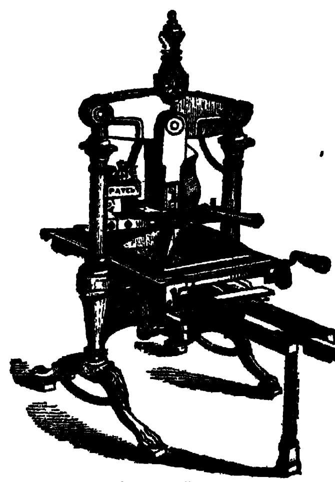
It is in the actual process of PRINTING, or the impressing stage of the art, that marked advancement is to be found, but the more important developments may be traced from a period as recent as the beginning of the nineteenth century. Until that time nearly all printing was done on hand presses, and then only by one or two pages at a time. The first printing press was probably an adaptation of some domestic appliance, the impression being obtained by means of a wooden screw forcing a wooden platen on to the forme, which was placed on a flat stone bed. The wooden press continued in use for three centuries and a half. In the year 1800 Lord Stanhope introduced the first distinct improvement. The wooden screw was abandoned in favour of a system of levers, and the size of the press was increased. Further, it was built entirely of iron, and consisted of a heavy frame in one piece, screwed to a wooden foundation called the "cross." By a combination of levers the platen was made to descend with increasing force until it reached the type or forme. From this time improvements have been continuous. The Stanhope press gave way to the Columbian and Albion presses. The essential parts of the Columbian are stronger than those of the Stanhope, and the recovery of the platen is self-acting. The Albion press is typical of the hand presses now in use. It is lighter and stronger, and more compact than the earlier makes. The process of printing on hand presses is very simple. The forme is laid on the iron bed and fastened to the flanges. The surface of the type is inked by means of a roller. Attached by joints to the end of the press bed is a tympan, consisting of a thin iron frame, over which is stretched a skin of parchment. This is backed up by another thin frame, also covered with parchment, which fits into the tympan frame by means of hooks. Between the two parchments is placed a number of sheets of paper, so that the whole forms a pad into which are also placed the extra sheets prepared in "making ready" (*q.v.*) Each sheet of paper to be printed is placed on the surface of the tympan and lowered on to the forme of type which has already been inked. The bed is then passed under the platen of the press, and the impression made by drawing over a bar actuating certain levers and causing the platen to descend. The frisket—an iron frame over which a sheet of paper is pasted—is sometimes hinged to the top of the tympan. The paper on the frisket is cut away in places where the type is to be printed, and, being laid over the white sheet, falls upon the forme and preserves the margins clean. Originally the formes of type were inked by balls made of cotton wool covered with skins or pelts. With these the face of the type was beaten until a sufficient quantity of ink was distributed. They were superseded by "rollers," which are composed of a mixture of glue and treacle, and these, in improved form, are now in general use.



GUTENBERG'S PRESS.

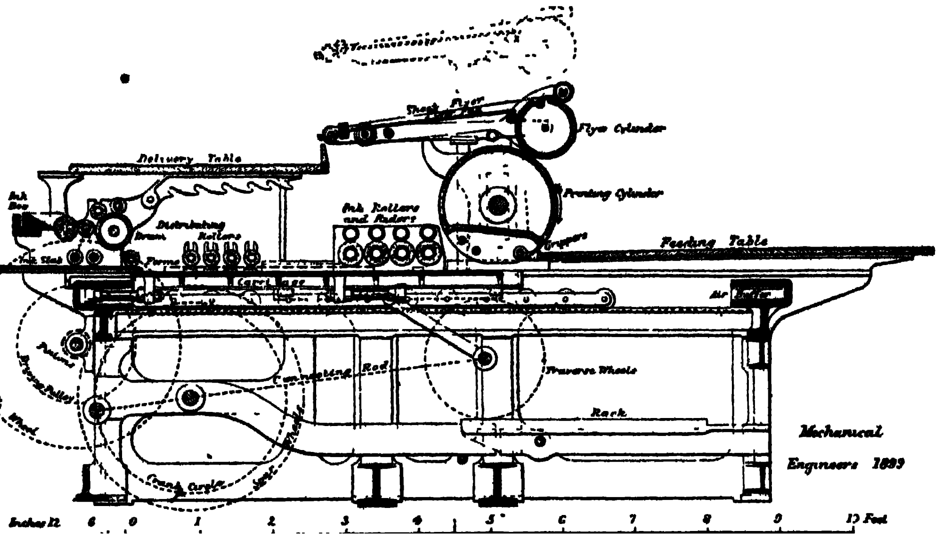


COLUMBIAN PRESS.



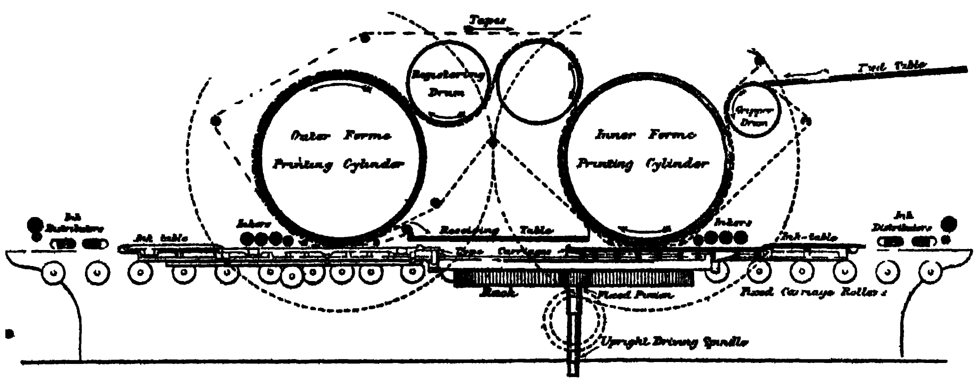
ALBION PRESS.

The term machine, as applied to printing, may be said to have been first used in connection with a mechanism invented by Nicholson, of London, in 1790, worked by steam, and improved by Kœnig about 1807. In this the principle of impression by platen was discarded, and a revolving iron cylinder used to force the paper on to the forme. This machine attracted the attention of Mr. John Walter, revolves in sympathy with the reciprocating motion of the bed. The sheet of paper is presented from a feed board to the edge of the cylinder, which is fitted with a bar running the whole length. Grippers are fixed upon the bar at intervals. The grippers secure the sheet until the cylinder has revolved over the surface of the type, when it is released and carried by tapes or flyers on to the



English Wharfedale Machine.

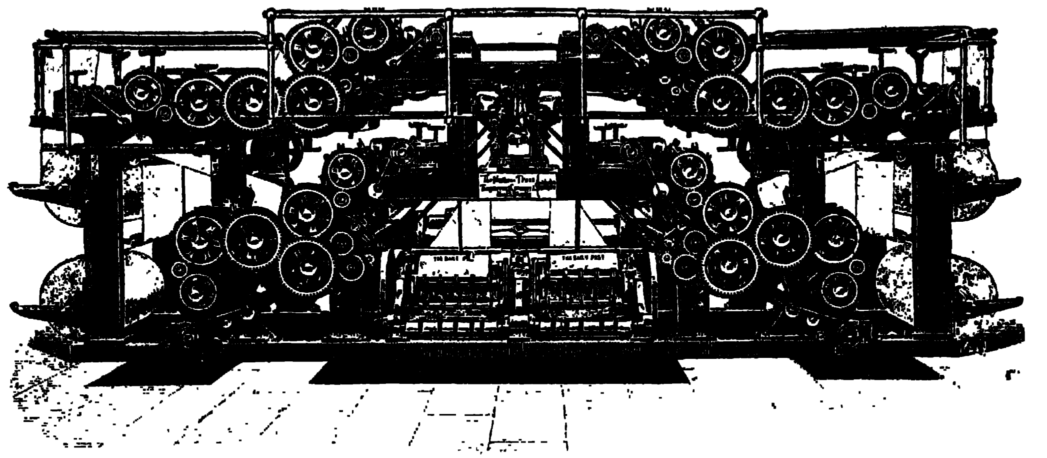
of *The Times*, who ordered one of the same principle to print that newspaper. The machine had two cylinders, was driven by steam, and made about 1,800 impressions in an hour. This cylindrical machine is the basis of all modern advances. Improvements in inking arrangements were made, and the number of cylinders increased until 9,600 delivery board, being printed on one side of the paper only. During the reciprocating movement of the bed the forme is inked by rollers running in forks fixed to the side frames. The ink is contained in a "duct" fixed at the end of the frame of the machine. This duct is in immediate contact with a distributing drum, from which a supply of ink is



Perfecting Machine.

impressions per hour were produced. Of the *Single Cylinder* machine the English Wharfedale best serves as a type of the whole. This machine has two side frames and four cross frames with longitudinal stays. These carry a flat bed or "coffin," upon which the forme travels backwards and forwards. The cylinder is supported on brackets fixed to each of the side frames in the centre, and conveyed by the "vibrator," or roller with a vibrating motion, to a flat iron slab at the end of the reciprocating bed, on which it is evenly distributed by the "wavers." The ink is then taken from the slab by the "inkers" and deposited on the forme. Many improvements in details have been introduced of late years, including the gearing of rollers, by which means their revolutions are

controlled; automatic feeding and "taking off" attachments; special bed and cylinder movements, etc.; but the principle of the machine is not materially altered. Many of the changes made are of American origin, and have resulted from the demand for high class illustrated works and the introduction of the photographic process block, which require extreme rigidity in the construction of the machine, absolute sympathy in all movements, and strict control of ink supply. The actual process of printing is not an involved one. After "making ready," the machine works automatically, and prints the sheets as fed by the "layer on," the "minder" giving attention to the regular flow of ink, etc. The *Platen* machine is a type of vertical bed machine, and may be worked by treadle or steam power. The *Cropper*, or "*Minerva*," was the first to be made, and the general design of this machine is retained in all the newer productions. It consists of two side frames held together by iron stretchers, and to these frames all the working parts are connected. The type is locked up in special chases, and placed on the vertical bed in the back part, the inking arrangements being placed behind and above it. The front part consists of a platen, lying when idle almost flat, and on which the paper is laid to marks or gauges. When the flywheel revolves the platen is pulled forward into a vertical position by two strong arms, one on either side of the machine, and an impression is taken. As the platen returns to its original position, the operator removes the printed sheet and replaces it with a plain one. At the same time the rollers pass over the face of the type, inking it in readiness for the next impression. A large kind of single platen machine called the "*Scandinavian*" is used. Its original purpose was to supersede the hand press. There is also a *Double Platen* variety; but both are being discarded in favour of cylinder machines. *Perfecting Machines* are composed of duplicate mechanisms of the important features of single cylinder machines, with special attachments for reversing the sheet in order that both sides may be printed before it is released. The cylinders of the "Web," "drop bar," and "gripper" varieties are usually larger than is the case with single machines, and in order to avoid the "set off" occasioned by one side of the paper being printed quickly after the other, endless strips of oiled paper pass continually between the impression cylinder and the printed sheet. Of this type of machine there are many varieties, and their purpose is to effect more rapid production. Other Perfecting machines having smaller cylinders are built, and as they possess some of the special advantages of the single machine, are capable of printing work of a much higher character. In *Rotary* machines the printing surfaces as well as the impressing surfaces are cylindrical, and for this reason special stereotype or electrotype plates are now made and curved to conform with the cylinder. The machines vary somewhat in principle: in at least one case the cylinders are arranged in semicircular form, in others on a horizontal plan; the more modern idea is to arrange them vertically. The rotary style of machine dates from 1848, when Applegarth built a machine for printing the *Times*. The type was arranged on a vertical central cylinder, around which were placed eight other vertical cylinders, to each of which there was a feeder, which fed single sheets down a sloping cylinder, to be carried by tapes towards the printing cylinder. When the impression was taken the sheet was carried back horizontally by tapes until it arrived at another table, when, being released by the grippers, the "taker off" disengaged it. The product of the machine was nearly 10,000 copies per hour. Another machine giving nearly 20,000 copies per hour on one side of the paper only was invented by Colonel Hoe, of New York, and used for printing *Lloyd's Newspaper* about 1857. This machine also printed single sheets from movable types. In 1868 Mr. John Walter perfected a machine to print on both sides of the paper from a continuous roll. Further improvements continued to be made, and machines are now capable of printing simultaneously plates of different character in several colours of ink on paper of varying sizes. Being fitted also with folding, pasting, and wire stitching attachments, it is possible to produce complete magazines at the rate of 24,000 per hour. The earlier types of rotary machines were used exclusively for printing newspapers, but it is now possible to produce by



English Rotary Machine.

the more modern variety illustrated work of a fairly high character. A recent type of newspaper machine—Hoe's Octuple—measures 35 ft. in length by 10 ft. in width and 15 ft. high. It has eleven pairs of printing cylinders, forty ink distributing cylinders, 100 composition rollers, twenty-two ink fountains, and 850 gear wheels. In all it is composed of about 50,000 separate pieces. *See also* PHOTO-ENGRAVING, TYPEFOUNDING, TYPES, *and* TYPE SETTING MACHINES.—R. J. E.

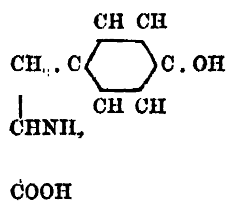
Tyre (*Eng.*) In engineering, etc., a tyre is usually a ring or hoop of iron or steel, encircling the wheel of a vehicle. It may be fixed on by bolts, rivets, etc., by shrinking (*q.v.*) *See* RAILWAY WHEELS.

Tyres, Rubber. The shocks imparted to a vehicle by the irregularities of the road over which it passes may be classified under two main heads: (*a*) The severe shocks, which occur at considerable intervals. (*b*) The minor shocks, which are practically perpetual. To absorb the first class, carefully tempered springs are used on all pleasure and on most commercial vehicles; while the second class is combated by encircling the wheels with rubber tyres. The bicycle has been mainly responsible for the introduction of the rubber tyre, the object being to prevent vibration. The early "boneshaker," iron-rimmed, carried a long and very elastic spring on which the saddle rested. In the 'seventies the SOLID RUBBER TYRE appeared, and did duty on the high bicycle and the earlier patterns of safety cycles. This gave way to the CUSHION TYRE, of tubular section, and was in turn succeeded by the pneumatic air-cushion tyre, now, in its perfected form, generally used. The first PNEUMATIC TYRE was patented in 1846 by a Scotchman named Thompson, and was intended for a horsed vehicle. It had an outer covering of leather bolted to the wooden felloe of the wheel. As there were no light vehicles on which to test and perfect this invention, Thompson's idea proved commercially unsuccessful, and was soon forgotten. Mr. J. B. Dunlop, a veterinary surgeon of Belfast, claims the distinction of first fitting a pneumatic tyre to a cycle wheel. It consisted of an inner tube of sheet rubber, encased in a canvas cover, outside which was solutioned a stout rubber strip. He patented his invention in 1888, and fitted it to racing machines with much success. The "mummy" tyre was attached to the rim by a strip of thin canvas, slit at intervals to pass round the spokes, and made to adhere to the outer cover by rubber solution smeared along its edges. The mending of a puncture in a "mummy" proved so laborious and uncertain that the pneumatic tyre would never have become popular in that form. Various devices—flaps in the tyre itself, manholes in the rim through which the tube might be pulled for repair—were tried, without success. In 1890 two types of DETACHABLE PNEUMATICS appeared: (*a*) the "wired on," patented by Mr. Chas. Kemp Welch; (*b*) The beaded-edge tyre of Mr. W. E. Bartlett. The WELCH COVER depends for its efficiency on the shape of the rim, which is U-shaped. The wired edges of the cover form circles somewhat smaller than the edges of the rim, and can be detached only if one side be pressed well down into the centre of the rim, so as to give the other side a requisite amount of slack. The beaded-edge type is held on by the pressure of inflation, its thickened edges engaging with the turned over edges of the rim. These two patents have been modified since, but not superseded. The CLINCHER and PALMER TYRES are covered by the Bartlett patent, which was purchased by the Dunlop Pneumatic Tyre Company, along with the WOODS VALVE and WESTWOOD RIM patents, before the flotation of that company in 1896. In the first tyres the valve was merely an elastic indiarubber tube closed by a wooden plug. The valves which have replaced it are, like the covers now used, of two main types: (*a*) The metal valve, made airtight by the careful grinding of the valve on its seat. (*b*) The Woods valve, a metal nozzle closed at the inner end and pierced at one side to permit the passage of air. A short length of tube rubber covers this hole, and is pinched at its outer end against and between the nozzle and a seating on the cylindrical body communicating with the inner tube of the tyre, so as to form a simple non-return. The FLEUSS TYRE possesses no inner tube, but the edges of the cover overlap and fit together closely enough to retain the air. The pneumatic tyre, being extremely elastic, minimises the vertical shocks caused by encountering undulations, irregularities, or obstacles on the road's surface. Slight shocks are practically "killed" before they can reach the springs supporting a saddle or vehicle. It thus obviates the loss of power caused by a heavy body being thrust repeatedly in a direction other than that in which alone it should travel. A second advantage is the ability of an air cushion of this type to recover its original shape so rapidly after distortion that it may be said to give a backward kick to an obstacle, which practically compensates for the obstruction to movement caused by its compression. Solid rubber, of a section equal to that of a pneumatic tyre, has much less elasticity and a much slower rate of recovery, and therefore is much less efficient in the foregoing respects.

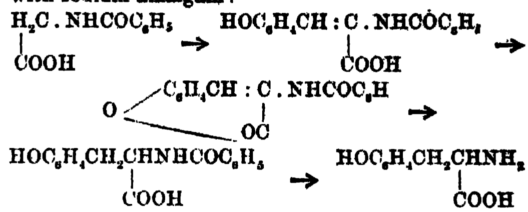
RUBBER TYRES FOR MOTOR VEHICLES.—Motor cars are usually pneumatic shod, in order to be able to move at high speeds without excessive vibration and wear and tear in the working parts. Commercial vehicles and delivery vans employ solid rubber tyres. PNEUMATIC MOTOR TYRES are generally constructed on the beaded-edge principle; but owing to the great strain, especially on the tyres of the driving wheels, they do not depend entirely on the pressure of inflation to keep them tight against the rim. Four or more "security winged bolts," passing at intervals through the rim, are furnished with V-shaped plates, which press on the inside of the cover when their screws are tightened up. These not only make it difficult for the cover to blow off, but also prevent it from "creeping" and tearing out the valve. The Sirdar Tyre Company has produced a tube of a nature which minimises the danger of nipping when it is placed in its cover. The tube is vulcanised in a U-section, so that when deflated, one half springs up into the crown of the other half. When inflated, it assumes a circular shape; but, being rather larger in section than the inside of the cover, the rubber is under compression, and therefore less vulnerable to punctures than a tube which is extended during inflation. Among wired-on motor pneumatic tyres, the PETER UNION may be noticed. The flange on one side of the rim is detachable. It is of circular shape, and split at a point to allow it to pass over the rim when an adjusting screw, working in left and right handed threads in blocks on its free ends, has been turned sufficiently. When the flange is placed in position and the screw has been tightened up, the tyre cannot possibly leave the rim. Heavy car pneumatic tyres are often inflated to a pressure of 120 lb. to the square inch, which approximates the working pressure of some locomotive boilers. Light

car tyres are pumped to 75 lb. to the square inch, and voiturettes to 50 lb. In construction they differ little from the corresponding types of cycle tyres, except that the treads are made disproportionately thick to withstand the very severe work they must do. The replacement of tyres may cost anything up to £50 a set of four. A fast and heavy tourist car is said to wear out its tyres at the rate of sixpence a mile. A violent application of the brakes may cause several pounds' worth of damage by grinding a "flat" on the tyres. SOLID RUBBER TYRES have several advantages. They are more reliable and wear longer than pneumatics, do not raise so much dust, and seemingly are not so prone to sideslip. A good set of "solids" have done duty for 10,000 miles on a heavy vehicle before being worn out. Solids are not, of course, as comfortable to travel on as pneumatics. To obtain a maximum of resiliency, without having recourse to compressed air, the DOUBLE ARCH TYRE has been introduced. It consists of two parts, the outer portion being of special high quality wear-resisting rubber, having a central arch, in which is fixed a sort of small inner tyre of a softer and more elastic nature. The popular method of attaching a solid tyre to its rim is the beaded edge, gripped by removable flanges. Some makers, however, use endless wires embedded in the rubber. For very heavy vehicles, such as motor omnibuses, two, and even three, solid tyres are mounted side by side on a single rim. This method is calculated to give greater freedom from sideslip and a greater amount of resiliency than would be possible with a single tyre of larger section. Many anti-skid and anti-wear devices have been tried for pneumatic tyres. They generally take the form of leather bands, covered with steel studs, and are vulcanised to the outside of the cover. The Parsons anti-skid—a series of short chains crossing the tyre in zigzag fashion, and attached to a wide circle on each side—have proved successful. It may be said of all these devices that while fulfilling their office in a greater or lesser degree, they tend to "slow" the tyre.—A. W.

Tyrosine (*Chem.*)



(Parahydroxyphenol-α-aminopropionic acid). Forms delicate white needles; melts at 235°; very sparingly soluble in cold water (1 in about 2000), but more soluble in boiling water; very slightly soluble in alcohol, insoluble in ether; dissolves in acids or alkalis, forming salts with both; it contains an asymmetric carbon atom, so that naturally occurring tyrosine is active (lævo-rotatory). On heating it loses carbon dioxide and forms parahydroxyphenylethylamine, $H_2N.CH_2CH_2.C_6H_4OH$: treated in water with putrefying pancreas it gives hydroparacumaric acid, $HOOC.CH_2.CH_2C_6H_4OH$: with Millon's reagent (*q.v.*) it gives a red colour: boiled with a dilute formaldehyde to which concentrated sulphuric acid has been added it gives a green colour. It is a product of the hydrolysis of many proteids, *e.g.* casein, keratine, fibroin of silk. It occurs in urine in certain liver diseases, and in phosphorus poisoning: it has been found in plants. Tyrosine can be prepared by boiling white silk (free from gum) with dilute sulphuric acid (100 grs. silk: 200 cc. H_2SO_4: 1000 cc. water) for twelve hours, exactly neutralising with barium hydroxide solution, filtering, extracting the barium sulphate with water, and evaporating the filtrate and extracts to crystallisation. The crude tyrosine is extracted with glacial acetic acid, and the residue dissolved in hot water and boiled with animal charcoal—the filtrate deposits tyrosine. Tyrosine has been synthesised by condensing parahydroxybenzaldehyde with hippuric acid by means of sodium acetate and acetic anhydride: the resulting anhydride of parahydroxy-α-benzoylaminocinnamic acid yields racemic benzoyl tyrosine on reduction with sodium amalgam:



The racemic benzoyl compound can be resolved by brucine (l-form is the less soluble), and on hydrolysis it yields l-tyrosine.

U (*Chem.*) The symbol for URANIUM (*q.v.*)

U Leather (*Eng.*) A leather collar whose section is of the form of the letter U. *See* HYDRAULIC PRESS.

Ulexite (*Min.*) A hydrous calcium sodium borate: $NaCaB_5O_9.8H_2O$, containing 45·6 per cent. of boracic acid. It occurs in opaque white masses, often with Gypsum and Alum. From Iquique, Nova Scotia, California, etc.

Ultimate Strength (*Eng.*) The ultimate strength is the total load which is necessary to break a structure or a given piece of material.

Ultra-Basic Rocks (*Geol.*) Eruptive or igneous rocks, containing less than 45 per cent. of silica. The most characteristic mineral is Olivine: on this account they are often termed PERIDOTITES, from Peridot (*q.v.*)

Ultramarine (*Chem.*) The blue colouring matter of lapis lazuli. On account of its beautiful blue colour it is much valued as a pigment. Formerly it was obtained by grinding the costly lapis lazuli, but now it is prepared artificially on a very large scale. It contains the elements Al, Na, Si, S, and O; but owing to the variation in composition of the ultramarine made by different people, and even by the same people, its formula cannot be regarded as settled. There are ultramarines of several different colours—blue, blue-violet, green, red, and white. As ultramarines of the same colour vary somewhat in composition, it must be said that if, say, blue ultramarine is a definite compound, it has not yet been prepared in a state of purity. An analysis of one of the best blues (Hoffmann) gave Na 17·14, Al 16·25, Si 18·33, S 8·42, and O 39·86 per cent. From this and a large number of other analyses Heumann deduces the formula $Na_6Al_4Si_4S_2O_{16}$ for pure blue ultramarine. The violet-blue ultramarines are richer in silica. White ultramarine is obtained when the roasting of the charge (*see* below) is carried out in absence of air. When the white ultramarine is heated in oxygen

it passes into blue ultramarine, and when the blue variety is heated with sodium carbonate and carbon it passes into the white. Green ultramarine is believed to be a transitional form between the white and blue. Red ultramarine is formed in the preparation of the blue when the charge has been strongly heated and much exposed to air. Besides ultramarines containing sodium, others containing silver, potassium, or lithium, in place of sodium, have been prepared. Ultramarines containing selenium (brown and purple-red) and tellurium (yellow and green), in place of sulphur, have also been prepared. The various blue ultramarines are most used, and next to them the green. In the preparation kaolin, sodium carbonate, sodium sulphate, charcoal (with or without resin), and for silica rich products some form of silica, are used. The materials must be pure, finely divided, and intimately mixed. Their proportions are decided on from the nature of the product required, the experience of the makers, and the method of roasting. If green as well as blue products are required, the charge is roasted in crucible-shaped vessels in ovens, and when the roasting is completed the charge is ground with water and washed. This product is green and ready for use; but if blue is required, it is now heated with sulphur with access of air, and at a lower temperature than before. A part of the sodium is thus removed as sodium sulphate, which dissolves in the washing water. When blue only is required, the operation can be completed in one stage, the charge being protected from air after the roasting is finished till it has cooled down. The product in any case is well washed to remove sodium sulphate, then ground and run into settling tanks, the finest divided settling slowest. Finally the various products are dried. Ultramarine is unchanged by heating, except at a very high temperature, when it becomes white; and acids liberate sulphur dioxide from the white product. Alkalis do not change it, except at a high temperature; but acids easily act on it—*e.g.* hydrochloric acid liberates sulphuretted hydrogen, converts the sodium into chloride which dissolves, a part of the aluminium into chloride which dissolves, a part of the silica into silicic acid which also dissolves, while some sulphur, silica, and alumina remain undissolved. A warm solution of alum easily decomposes the silica-poor ultramarines; but only acts slowly on the silica-rich varieties. Oxidising agents at a high temperature readily decompose all ultramarines. Besides being used as a pigment, ultramarine is much used in making laundry blue, and in "correcting" the yellow colour of paper, linen, sugar, etc., in making blue printing ink, writing paper, mottled soap, etc.

Ultramarine (*Paint.*) A blue pigment largely used by house painters, printers and others, and made by heating together a mixture of china clay, soda ash, sulphur, sodium sulphide, sodium sulphate, and resin. The manufacture of ultramarine is in the hands of a very few firms, and paint makers invariably purchase it ready made. It varies largely in composition according to the purpose for which it is to be used. It works well in distemper and in oil, but must not be mixed with white lead. Originally ultramarine was made for artists' use from lapis lazuli, but this is now almost wholly discontinued, the cost being very great.

Ultra-Neptunian Planets (*Astron.*) Possible planets that may revolve round the sun at a greater distance than Neptune.

Ultra-Violet Rays (*Phys.*) Rays whose wave length is too short to excite the sensation of vision. They accompany in greater or less degree the visible radiation from most sources of light, and constitute an invisible prolongation of the spectrum beyond the violet. They may be easily detected by photographic means or by allowing the rays to fall upon a screen such as is used in Röntgen Ray experiments, when fluoresence is produced.

Umbelliferæ (*Botany*). A natural order of Dicotyledons containing many plants of economic value. The Carrot, Parsnip, Celery, are well known vegetables, while Caraway, Coriander, Fennel, Anise, etc., enter into pharmaceutical preparations.

Umber (*Min.*) An earthy variety of Limonite, used as a pigment. It is found in the Isle of Man, in the Forest of Dean, Saddleback, in Cyprus, etc.

—— (*Paint.*) A natural earth of a brown colour which is sold as "raw umber" and "burnt umber," the latter being subjected to heat which intensifies the colour. Umber is largely used by grainers for obtaining rich, deep effects, and by house painters to assist in producing many dark, rich colours and also for lessening the brilliancy of mixed colours in general. They are comparatively cheap, quite permanent, and may be safely used when ground either in water, turpentine, or oil.

Umbo (*Arm.*) The boss or knob, sometimes terminating in a spike, in certain forms of shield, especially the small round shield or buckler. The term was sometimes applied to the shield itself.

Umbra. The darkest central portion of the shadow cast by a body. It is surrounded by the penumbra (*q.v.*)

Umbrian School of Painting. *See* PAINTING, SCHOOLS OF

Una Corda (*Music*). A sign indicating that the left pedal of the pianoforte is to be used. By this pedal the action is moved slightly to the right, causing the hammer to strike only two of the three strings of each note. Formerly only one string (*una corda*) was struck. Some makers cause a strip of felt to drop between the hammers and the strings when the left pedal is depressed. This gives to the notes a muffled sound, an effect very different from that intended by *una corda*, which produces a tone of delicate and special quality. The direction *tre corde* (three strings), or *tutte le corde* (all the strings), indicates that the left pedal is to be discontinued. Beethoven, in the pianoforte Sonata in B♭, Op. 106, has the following direction after *una corda: poco a poco due ed allora tutte le corde* (gradually two and then all the strings), indicating the gradual release of the left pedal (*see also* PIANOFORTE, *p.* 429). On stringed instruments *a una corda* shows that the whole passage is to be played on one of the strings only.

Unbuilding (*Elect. Eng.*) The demagnetisation of the field magnets of a dynamo or motor.

Uncaria Gambier. A climbing plant (*Rubiaceæ*) from Polynesia and Singapore. The young shoots and leaves yield an extract, CATECHU (*q.v.*)

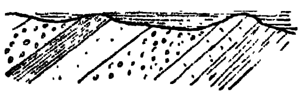
Uncial. The term is used to denote the style of writing found in early manuscripts (4th—9th centuries) before the introduction of the "new" cursive

hand. Uncial characters resemble modern capitals, but are rounder in form:

Uncial: ΚΑΙΕΓΕΝΕΤΟΕΝΤΩ
Capitals: ΚΑΙΕΓΕΝΕΤΟΕΝΤΩ

In Greek palæography the distinction between the capital and the uncial is insignificant, except that the latter is more rounded in outline, but in Latin MSS. the difference is much more marked. The uncial continued in use until the 9th century, the style of the transition period being known as the SEMIUNCIAL. Uncials were employed in the books of the Church until a much later period. *See* MAJUSCULE and MINUSCULE (Appendix)

Unconformity (*Geol.*) The relationship of a set of newer rocks to an older set of rocks which have been tilted, or otherwise disturbed, and have undergone denudation before the newer ones were deposited. The new rocks thus lie across the edges of the older ones, as in the diagram. *See also* CONFORMABLE SUCCESSION.



UNCONFORMITY.

Unda Maris (*Music*). An organ stop which produces a tone of a waving character similar to the Voix Céleste. The term means sea wave.

Undée *or* **Wavy** (*Her.*) Wavy or undulating: one of the partition lines. *See under* HERALDRY.

Undercut (*Eng., etc.*) This term is applied to parts of an object below some other overhanging portions; to re-entrant angles (*q.v.*), etc. Also applied specifically to (1) parts of patterns whose diameter increases towards the bottom, and which therefore cannot be withdrawn from the mould in the ordinary way; (2) various operations that are carried out from the underside, *e.g.* in mining, as well as to machines arranged to operate from the underside; (3) a carving or moulding that has the parts in relief partially cut away or bevelled on the underside.

Under Glaze Decorations (*Pot.*) Decorations which are placed upon the bisque ware, to be afterwards glazed and burnt in the glost oven. *See* BISQUE.

Underground Conductor (*Elect Eng.*) A name applied either to (1) an insulated wire which may be cased with damp proof material and laid directly in the earth, or may be carried in a conduit or pipe; or (2) to the bare conductor of an electric tramway on the slotted conduit system. *See* ELECTRIC TRACTION.

Underground Railways (*Civil Eng.*) Underground railways are conveniently divided into two types—the shallow tunnel with numerous open cuttings (*e.g.* the Metropolitan and District Railways) and the deep level or Tube Railways (*e.g.* Central London). The former is largely constructed on the "cut and cover" plan, open cuts being made and afterwards arched over, actual tunnelling being avoided as much as possible; while the latter are continuous tunnels, with linings of tubular form, built up of segments of cast iron. Separate tunnels are generally used for the up and down lines, each tunnel having a diameter of 10 to 12 ft. The stations are contained in short lengths of tunnel of larger diameter, the linings being of brick. The approaches are formed by tubular shafts containing electric or hydraulic lifts, with auxiliary staircases in some cases. The depth at which these lines are constructed is sufficient to prevent interference with sewers and pipes; but the vibration produced is very distinctly felt in buildings in the vicinity. The City and South London line cost about £220,000 per mile.

Underground Temperature (*Meteorol.*) For the measurement of the penetrative powers of the solar heat rays into the earth's surface, thermometers of various construction are placed at different depths and read regularly.

Underlay (*Print.*) Resembling an overlay (*q.v.*) in character, but placed beneath instead of above the block to be printed.

Underpin (*Build.*) To support or renew the foundation of a wall, etc.

Underpick (*Weaving*). A picking motion in which the picking arm is under the shuttle box. A very common motion in quick running looms. *See* OVERPICK *and* PICKING.

Under Poled (*Met.*) *See* COPPER *and* POLING.

Undershot Wheel (*Eng.*) A water wheel in which the water acts only on those floats that are near the bottom of the wheel. It therefore depends for its supply of energy on the velocity (*i.e.* the Kinetic Energy) of the water, which may be flowing along a perfectly horizontal channel while passing under the wheel.

Undertype Magnet (*Elect. Eng.*) The field magnet of a two-pole dynamo or motor which has its poles (and therefore the armature) next to the base plate.

Undulations (*Phys.*) An expression generally used as equivalent to Waves. *See* WAVE MOTION.

Undulatory Discharge (*Elect.*) An OSCILLATORY DISCHARGE (*q.v.*)

Undulatory Theory of Light. The WAVE THEORY (*q.v.*)

Undulatory Winding (*Elect. Eng.*) *See* WAVE WINDING.

Unequal Temperament (*Music*). The old system of tuning which gave certain keys correctly in tune, whilst leaving others unusable.

Unessential Notes (*Music*). Passing notes and auxiliary notes (*q.v.*)

Unguentarium (*Archæol.*) A vase used for holding oil, etc., for anointing the body.

Unhairing (*Leather Manufac.*) The process of removing hair from hides and skin, previous to tanning. *See* SWEATING *and* LEATHER MANUFACTURE, *p.* 349.

Uniaxal Crystals (*Phys., Min.*) A crystal having one optic axis. *Cf.* BIAXAL CRYSTAL *and* DOUBLE REFRACTION.

Unicorn (*Her.*) A fabulous animal occurring sometimes as a charge in heraldry. The body is that of a horse with the legs of a buck and the tail of a lion, a single straight horn growing out of the forehead. The unicorn is one of the supporters of the Royal Arms of Great Britain.

Unidirectional Current (*Elect.*) A current flowing in one direction only as opposed to an alternating current.

Union (*Build.*, *Eng.*, *etc.*) A device for connecting the ends of two pieces of pipe. In the simplest form it consists of a threaded tubular socket, into which the ends of the pipes are screwed.

—— (*Textile Manufac.*) A fabric composed of two or more materials, such as cotton warp and mungo weft, worsted warp and woollen weft.

Union Blanket. *See* BLANKET.

Union Wrench (*Eng.*, *etc.*) A lever, one end of which is curved so as to fit against a union (*q.v.*), a pin in the curved end fitting into a hole in the union to enable it to be turned by the lever.

Unison (*Music*). Two or more notes of the same pitch, *i.e.* having the same number of vibrations per second, sounded together (*see* INTERVALS). When vocal or instrumental passages are performed in octaves they are sometimes, though incorrectly, said to be in unison.

Unit. A selected quantity, whose amount is fixed and invariable, used as a standard of comparison in stating or determining the amounts or values of other quantities of the same nature. The numerical value of any quantity is the number of times which it contains the chosen unit, or in other words the ratio of the magnitude of the quantity to the magnitude of the unit. *See also* UNITS, FUNDAMENTAL *and* DERIVED.

Unit Charge of Electricity (*Elect.*) A charge of electricity such that if placed at one centimetre in air from an equal quantity, it exerts on it a force of one dyne (all other electrical forces being absent, and the two charges being supposed to be concentrated at mathematical points).

Unit Jar (*Elect.*) A small Leyden jar used to measure roughly the electrical capacity of a larger jar or condenser.

Unit of Heat. *See* CALORIE.

Unit Pole (*Magnetism*). A pole such that if placed at unit distance in air (or other material whose magnetic permeability is unity) from an equal pole, it exerts on it a force of one dyne (all other magnetic forces being absent, and the two poles being assumed to be mathematical points).

Units, Absolute System of (*Phys.*, *etc.*) A system based upon certain fundamental units (*e.g.* the units of mass, space, and time) from which all others are derived by means of certain definite physical relations.

Units, Dimensions of (*Phys.*) *See* UNITS, DERIVED.

Units, Fundamental and Derived. The fundamental units generally chosen are those of LENGTH, MASS, and TIME. In most scientific work the centimetre, gram, and second are used, though the foot, pound, and second are also used (*see* WEIGHTS AND MEASURES). From these three fundamental units others, termed DERIVED UNITS, are obtained. Thus the unit of area depends upon the square of the unit of length, but not in any way upon the units of mass and time. This is expressed in scientific language by saying that the DIMENSIONS of this unit are 2, 0, 0, with respect to length, mass, and time. This relation is shown by a DIMENSIONAL EQUATION thus:

$$A = L^2M^0T^0.$$

The unit of volume has similarly dimensions 3, 0, 0 with reference to the three fundamental units.

The chief units used in mechanics and their dimensional equations are as follows;

Velocity	$V = LT^{-1}$
Acceleration	$A = LT^{-2}$
Force	$F = LMT^{-2}$
Work	$W = L^2MT^{-2}$

See also DYNE, ELASTICITY, ERG, POUNDAL, FOOT-POUND, HORSE POWER, *etc.* The units used in heat require a fresh unit, that of temperature, whose dimensions with respect to length, mass, and time are unknown, and which is therefore represented by a separate symbol, θ. It has been termed a SECONDARY FUNDAMENTAL UNIT. The ordinary scientific unit of heat, the CALORIE (*q.v.*), has dimensions

$$Q = M\theta.$$

See also ABSOLUTE TEMPERATURE, CONDUCTIVITY, DIFFUSIVITY, ELASTICITY, JOULE, JOULE'S EQUIVALENT, *etc.* For units used in Light, see PENTANE STANDARD, PHOTOMETRY, STANDARD CANDLE, *etc.*

The electrical and magnetic units are derived from the mechanical units, but also require the introduction of the permeability, μ (*q.v.*), and specific inductive capacity, K (*q.v.*), of the media in which the electrical and magnetic phenomena are taking place in order to be complete. Two systems of units are in use. The first is the ELECTROSTATIC SYSTEM OF UNITS, in which unit charge is defined as that which exerts unit force on an equal quantity placed at unit distance from it in air. The dimensions of this unit are given in the equation—

$$Q = L^{\frac{3}{2}}M^{\frac{1}{2}}T^{-1}K^{\frac{1}{2}}.$$

From the unit charge the units of force, potential, capacity, etc., are obtained.

In the second or ELECTROMAGNETIC SYSTEM the dimensions of the unit of quantity are expressed by the equation—

$$Q = L^{\frac{1}{2}}M^{\frac{1}{2}}\mu^{-\frac{1}{2}}.$$

The unit current is that in which unit quantity flows across a given cross section of the conductor in unit time; the dimensions are given by

$$C = L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-1}\mu^{-\frac{1}{2}}.$$

This unit is otherwise defined in practice as follows: If unit length (1 c.m.) of the circuit carrying the unit current be bent into an arc of unit radius it will exert unit force (1 dyne) upon a unit magnetic pole placed at the centre of the arc. The AMPERE (*q.v.*) is one-tenth of this unit. UNIT DIFFERENCE OF POTENTIAL exists between two points if unit work (1 erg) be required to be done in order to transfer a unit quantity from one of the points to the other. The volt is 100,000,000 or 10^8 times this unit.

UNIT RESISTANCE is the resistance of a conductor in which unit current is produced by unit difference of potential between the ends. The OHM is 1,000,000,000 or 10^9 times this unit. *See also* AMPERE, CAPACITY CONDUCTANCE, COULOMB, JOULE, MAGNET, MHO, OHM, POTENTIAL DIFFERENCE, VOLT, WATT, etc.

Universal Chuck (*Eng.*) A chuck with self centering jaws. *See* SELF CENTERING CHUCK.

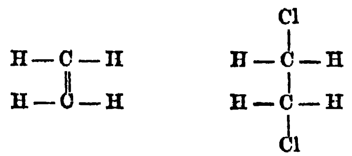
Universal Joint (*Build.*) A joint used in gas-fitting to connect two pipes in such a manner that one of them can be turned in any required direction.

—— —— *or* **Coupling.** *See* HOOKE'S JOINT.

Universal Machine (*Print.*) A small platen machine which may be worked by treadle or by power. *See* TYPOGRAPHY.

Unlock (*Typog.*) To loosen the quoins and furniture of a forme of type for the purpose of making corrections, etc.

Unsaturated Compounds (*Chem.*) A compound A is said to be unsaturated when a compound B can be prepared from it by direct addition of one or more than one atom or group of atoms in such a way that one or more than one atom in B is united to a greater number of atoms or groups of atoms than it was united to in A. Thus carbon monoxide is an unsaturated compound, because a compound carbon dioxide can be formed from it by direct addition of oxygen; and we believe the oxygen to be added in such a manner that, while the carbon atom in carbon monoxide is united to one atom of oxygen, the same atom is united to two atoms of oxygen in carbon dioxide. Again, ethylene is regarded as an unsaturated compound because it unites directly with chlorine to form ethylene chloride in such a way that, while in ethylene each carbon atom is united to two hydrogen atoms and one group CH_2, in ethylene chloride each carbon atom is united to two hydrogen atoms, one chlorine atom, and one group CH_2Cl. This is represented by formulæ as follows:



The double line joining the two carbon atoms in the formula for ethylene is the conventional way of indicating that ethylene is unsaturated, and unsaturated to the extent indicated by its union with two atoms of chlorine—that is to say, ethylene could conceivably add on something other than chlorine, but in such a case the atoms or groups added must be chemically equivalent to the chlorine. Calcium chloride is not ordinarily regarded as an unsaturated compound, in spite of the fact that it can unite with water, ammonia, and alcohol to form compounds, $CaCl_2 . 6H_2O$: $CaCl_2 . 8NH_3$: $CaCl_2 4C_2H_5OH$; for it cannot be shown that the calcium atom is united to any other element than chlorine in these compounds, and similarly for the chlorine. *See* VALENCY *and* WERNER'S THEORY.

Unsized Paper (*Print.*) "Blotting" and other very absorbent papers are manufactured without size. Papers in which only a small portion of the ingredient is used—technically called "soft sized"—are very suitable for printing illustrated or half tone work.

Unsound Food. *See* FOODS.

Unstable Equilibrium (*Phys., etc.*) *See* EQUILIBRIUM, UNSTABLE.

Unstratified Rocks (*Geol.*) A general term applied to Igneous or Eruptive Rocks, which do not occur in regular strata, but in more or less irregular masses, known as DYKES, VEINS, etc.

U Packing (*Eng.*) *See* U LEATHER.

Upcast *or* **Uptake** (*Mining*). A shaft in a mine for the upward passage of air.

Upheaval (*Geol.*) An upward movement of a portion of the Earth's crust; the resulting displacement of the rocks is accompanied by dislocations, faults, and other disturbances of the strata affected.

Upholstery. The business of fitting and "covering" furniture with various materials, *e.g.* springs, stuffing, coverings, trimmings, etc.; also the decoration of an apartment with textile fabrics, *e.g.* curtains, etc.

Upper Board (*Music*). (1) The board in which the feet of organ pipes stand. (2) The top board of the bellows on which the weights are placed. *See* ORGAN, *p.* 439.

Upper Case (*Typog.*) *See* TYPOGRAPHY, *p.* 803.

Upright Grand (*Music*). A grand pianoforte made to occupy a vertical instead of a horizontal position, to save space.

Upsetting (*Eng.*) (1) Shortening or thickening metal either by hammering or by machinery, as in the case of a wheel tyre. *See* JUMPING UP. (2) Spreading the teeth of a saw. *See* SAW SETTING.

Uptake (*Eng., etc.*) A flue leading from a furnace to a chimney.

—— (*Mining*). *See* UPCAST.

Uranic Ochre (*Min.*) A hydrous basic calcium uranium sulphate occurring in association with Pitchblende. It is a yellow powdery mineral. From Cornwall, Bohemia, and Connecticut.

Uraninite (*Min.*) A synonym for Pitchblende (*q.v.*)

Uranite (Copper) (*Min.*) *See* TORBERNITE.

—— **(Lime)** (*Min.*) *See* AUTUNITE.

Uranium (*Chem.*) U. Atomic weight, 238·5. A somewhat rare metal belonging to Series 12, Group VI. of the Periodic System (*q.v.*); it has the highest atomic weight of all the elements. Uranium is a white metal; melting point unknown, but high—in the electric furnace it volatilises more readily than iron. Specific gravity 18·7; in finely divided state it is easily oxidised in air, especially on heating, and it decomposes water slowly at ordinary temperatures, and quicker on heating; it is soluble in dilute hydrochloric and sulphuric acids. When heated to a high temperature (1000°) it readily combines with nitrogen, so that this gas must be excluded from the apparatus in preparing the metal. It reduces solutions of many metallic salts to the metal, *e.g.* Pt, Au, Ag, Hg, Cu, Sn. It occurs principally in pitchblende (*q.v.*), which contains 40 to 90 per cent. of the oxide U_3O_8. The metal is obtained as follows: The vapour of uranium tetrachloride is passed over red-hot sodium chloride to form the compound $2NaCl . UCl_4$, and this may be heated with sodium or melted and electrolysed (50 ampères, 10 volts) with carbon electrodes in an atmosphere of dry hydrogen. Uranium is a radioactive element (*see* RADIO-ACTIVITY and RADIUM). It differs from Thorium (*q.v.*) and Radium in not giving an emanation; α, β, and γ rays are emitted by uranium, but the γ radiation is the feeblest of the three. The metal owes its photographic properties chiefly to the β rays, its ionising action chiefly to the α rays. This can be proved by precipitating a uranyl salt solution with ammonium carbonate (*see* under Uranyl Nitrate), treating the precipitate with excess of ammonium carbonate, and filtering off the slight remaining

precipitate. The product, which is in extremely minute amount, is called UrX, and possesses all the photographic activity of the original uranium, while the uranium solution is photographically inactive, but electrically as active as before. While the activity of UrX decays (half in about twenty-two days), the uranium from which it was separated recovers its activity at the same rate. One gram of uranium emits about 70,000 α particles in a second, corresponding to a development of heat equal to ·3 gram-calories in a year. The β and γ rays contribute an amount of energy equal to about one per cent. of that due to the α rays. COMPOUNDS: Uranium carbide, U_2C_3, is a crystalline, metallic-looking solid; specific gravity 11·3. It is decomposed by water with evolution of a gas which contains about four-fifths of its volume of methane, the other fifth consisting chiefly of hydrogen and very small quantities of ethylene and acetylene, while two-thirds of the carbon of the carbide goes to form a mixture of liquid and solid hydrocarbons, saturated and unsaturated. When heated it burns brightly in oxygen, and for the same reason two pieces when rubbed together emit bright sparks. It is obtained by heating an intimate mixture of pure sugar charcoal and the oxide U_3O_8 in an electric furnace (900 ampères, 50 volts). OXIDES: Uranium dioxide, UO_2 (uranous oxide), is a brown powder; it is pyrophoric if obtained by heating uranyl oxalate out of air, or by reducing a higher oxide in hydrogen at as low a temperature as possible. When obtained by reduction at a high temperature it has a coppery lustre, and is not pyrophoric; strongly heated in oxygen or steam, it gives the oxide U_3O_8. Insoluble in water or hydrochloric acid, but soluble in nitric acid and in sulphuric acid containing only a little water forming, on boiling, uranous sulphate. It is obtained by heating the oxalate out of air, or by reducing the oxide U_3O_8 by heating in hydrogen. URANIUM TRIOXIDE, UO_3: A brick-red powder; loses oxygen on heating, forming the oxide U_3O_8. With acids it forms uranyl salts, with bases it forms uranates. It is obtained by heating the hydrate UO_3H_2O, or uranylammonium carbonate

$$UO_2 . CO_3 2(NH_4)_2CO_3,$$

or uranyl nitrate, at 250° to 300°. URANOSOURANIC OXIDE, U_3O_8 (uranyl uranate, $UO_2 . 2UO_3$, green oxide of uranium): This is the most important oxide of uranium. It is a powder varying in colour from a very dark green to black, but always gives a green streak. Insoluble in water, insoluble in dilute acids; soluble in nitric acid, giving uranyl nitrate; soluble in sulphuric or hydrochloric acids at about 200°, giving a mixture of uranous and uranyl salts. It is reduced to the dioxide when heating with reducing agents, or even on prolonged heating in an indifferent gas (N or CO_2). It is obtained by heating either of the two previous oxides or uranium nitrate in air. This oxide is the form in which uranium is contained in pitchblende; it is used to produce a black glaze on porcelain, and in the preparation of other uranium compounds. It is obtained from pitchblende by the following process: The ore is roasted with sodium carbonate containing a small quantity of sodium nitrate (the ore is sometimes roasted alone first), and the product is extracted with hot water, which extracts sodium salts of uranium (a little), molybdenum, tungsten, and arsenic; the residue is treated with a mixture of pretty strong sulphuric acid and a little nitric acid. The clear liquid is separated from the residue (it is this residue that contains radium, *q.v.*) and treated with excess of sodium carbonate; this solution is boiled to remove the last traces of iron and calcium. The filtered liquid, when cautiously neutralised with sulphuric acid, yields uranium yellow (sodium diuranate); if it is boiled with caustic soda it yields orange-coloured uranium yellow (probably another form of sodium diuranate); or if the liquid is treated with ammonium chloride it yields a precipitate of uncertain composition (an impure ammonium uranate) which yields the oxide U_3O_8 on ignition. URANIC HYDRATE, $MO_3 . H_2O$ or $MO_2(OH)_2$ (also called uranic acid), is a yellow powder, insoluble in water, but reddens moist litmus, and when hot absorbs carbon dioxide; on heating it yields first the trioxide (*q.v.*) and then the oxide U_3O_8. It is obtained by boiling an alcoholic solution of uranyl nitrate till no further oxidation of the alcohol occurs, washing the yellow solid so obtained and drying it in air, then *in vacuo*, or by exposing uranyl oxalate in water to sunlight, and washing and drying as before. URANATES may be regarded as derived from the preceding compound by replacement of water by basic oxides. Normal, di-, and poly- uranates are known ($R_2O . UO_3$, R_2O2UO_3, R_2OnUO_3, where R is a monovalent metal or group). Of the uranates the diuranates are the commonest. SODIUM DIURANATE, $Na_2U_2O_7 6H_2O$, is a light yellow or orange yellow powder obtained by adding insufficient or excess respectively of caustic soda to a uranyl salt solution (*see* Uranosouranic Oxide). It is used as a pigment under the name uranium yellow, and in making the fluorescent uranium glass (greenish fluorescence). CHLORIDES: A trichloride, UCl_3, is said to exist. URANIUM TETRACHLORIDE, UCl_4: Dark green octahedral crystals; volatilises at a red heat, and has a normal vapour density. Fumes in air, is deliquescent, and dissolves in water, forming a green solution; reduces gold and silver salts to the metal, and ferric to ferrous salts. It is obtained by heating a mixture of any of the above oxides with carbon in a stream of dry chlorine. Pentachloride, which is formed simultaneously, is decomposed by heating in an indifferent gas, such as CO_2. URANIUM PENTACHLORIDE, UCl_5, forms dark needles with green lustre or a light reddish-brown powder, according as it is formed by heating the tetrachloride in a slow or a rapid stream of dry chlorine respectively; when heated it decomposes. It is deliquescent, and when thrown into water evolves hydrogen chloride. URANOUS SALTS: Uranous chloride is the tetrachloride mentioned above. URANOUS SULPHATE, $U(SO_4)_2 4H_2O$, forms green crystals; on heating it loses sulphuric acid and forms uranyl sulphate; heated in hydrogen it gives the dioxide. It is formed by dissolving the oxide U_3O_8 in hot dilute sulphuric acid, adding alcohol, and exposing to sunlight, when the uranyl sulphate which is formed, as well as uranous sulphate, is reduced to the latter. It forms double salts with the sulphates of the alkali metals, *e.g.* $U(SO_4)_2K_2SO_4H_2O$. URANYL SALTS: Salts of the formula UO_2X_2, where X is a monovalent acid radical. URANYL CHLORIDE, UO_2Cl_2: A yellow crystalline solid, easily melted; soluble in water, alcohol, ether. It can be obtained by heating the dioxide in chlorine, or by dissolving uranic hydrate in hydrochloric acid and crystallising, when it separates with one molecule of water. URANYL NITRATE, $UO_2(NO_3)_2$, is often, but erroneously, called uranium nitrate. It is a yellow solid with green fluorescence, crystallising in columns or plates, and with $6H_2O$

from water; melts at 60°; loses the water at 118°; on strongly heating it gives the oxide U_3O_8. The salt is soluble in alcohol (*see* under Uranic Hydrate), also soluble in ether. It is phosphorescent. The solutions give an absorption spectrum, as do all uranyl salts. Ammonium carbonate gives a yellow precipitate soluble in excess of the reagent, owing to formation of uranylammonium carbonate, $UO_2CO_3 2(NH_4)_2CO_3$. Uranyl nitrate is made by dissolving any oxide of uranium in nitric acid and crystallising the solution. Uranyl phosphate, UO_2HPO_4, with a variable amount of water, is formed as a precipitate when a soluble uranyl salt is treated with a soluble phosphate; it is a pale yellow solid, very insoluble in water and dilute acetic acid. Its formation is utilised both gravimetrically and volumetrically in the estimation of phosphates. When heated it gives the pyrophosphate $(UO_2)_2P_2O_7$, in which form the precipitate is weighed in gravimetric analysis. Uranyl acetate, $UO_2(C_2H_3O_2)_2$, is made by heating uranyl nitrate till oxygen begins to be evolved, then dissolving the residue in warm, strong acetic acid and crystallising. On boiling its solution strong hydrolysis occurs. It is used in estimating phosphates volumetrically. Uranyl salt solutions give a reddish-brown precipitate with potassium ferrocyanide, and this reaction is so delicate that it is used as an indication of the end reaction in the estimation of phosphates volumetrically.

Uranium (*Min.*) Occurs only in combination in nature. The principal ores are Pitchblende, Autunite, Torbernite, Uranophane, Samarskite, Euxenite, Polycrase, Ånnerödite.

Uranus, Planet (*Astron.*) Distance from sun, 1,781,900,000 miles; diameter 31,900 miles; periodic time, 84 years. Four satellites (if not more), which move in a plane nearly at right angles to the Ecliptic (75°).

Uranyl Compounds (*Chem*) *See* URANIUM.

Urceus (*Archæol.*) A ewer, generally of metal, to hold water for washing. The diminutive is URCEOLUS.

Urea (*Chem.*) $CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2}$ (Carbamide).

White prisms; melts at 132°; very soluble in water; readily soluble in alcohol; insoluble in ether and in chloroform; it is a monacid base forming salts which are all soluble in water, the nitrate and oxalate being the least soluble—the nitrate is less soluble in nitric acid than in water, and therefore its formation is used as a test for urea. It unites with numerous metallic salts—*e.g.* with sodium chloride, forming $CO(NH_2)_2 . NaCl . H_2O$; with palladious chloride, forming $2CO(NH_2)_2 . PdCl_2$, which is very insoluble; with mercuric nitrate (when warmed with a dilute solution of urea), forming the basic compound $2CO(NH_2)_2 . Hg(NO_3)_2 . 3HgO$ (basis of Liebig's method of estimation of urea). When heated a little above its melting point, urea gives off ammonia and forms biuret (*q.v.*) and cyanuric acid:

$$2CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} = CO\genfrac{<}{}{0pt}{}{NH_2}{NH . CONH_2} + NH_3$$

$$3CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} = C_3H_3N_3O_3 + 3NH_3.$$

A solution of urea heated to 100° is partially transformed to ammonium cyanate (5 per cent.); but by adding silver nitrate so as to precipitate the cyanate, about 88 per cent. can be transformed; when boiled with alkalis, urea is hydrolysed:

$$CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} + 2HOK = CO(OK)_2 + 2NH_3$$

A number of bacteria and moulds hydrolyse urea to ammonium carbonate—some of these are widespread, occurring in air, soil, and water; the micrococcus ureæ is one of the commonest. Urea is decomposed, but not quite completely, by alkaline hypobromites, and less readily by alkaline hypochlorites:

$$CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} + 3NaOBr = 3NaBr + CO_2 + N_2 + 2H_2O$$

The carbon dioxide is completely absorbed if excess of caustic soda is used and the nitrogen alone escapes (basis of clinical estimation). Nitrous acid decomposes urea completely:

$$CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} + 2HNO_2 = CO_2 + N_2 + 3H_2O$$

In fairly strong solution urea reacts with phenylhydrazine in strong acetic acid solution to form phenylsemicarbazide, a white crystalline solid melting at 170°:

$$CO\genfrac{<}{}{0pt}{}{NH_2}{NH . NHC_6H_5}.$$

Urea yields a nitro-derivative—

$$CO\genfrac{<}{}{0pt}{}{NH . NO_2}{NH_2},$$

which is obtained by adding urea nitrate to concentrated sulphuric acid. It is a white crystalline solid which behaves as a strong acid; nitrourea is used in the preparation of semicarbazide (*q.v.*) Urea occurs in urine; an adult in health excretes about 1·5 litres of urine in 24 hours, and this contains from 21·5 to 34 grams of urea; it also occurs in the blood and perspiration. It can be obtained synthetically by gently heating ammonium carbamate—

$$CO\genfrac{<}{}{0pt}{}{NH_2}{ONH_4} = CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} + H_2O;$$

also by the action of ammonia on carbonyl chloride:

$$CO\genfrac{<}{}{0pt}{}{Cl}{Cl} + 2NH_3 = CO\genfrac{<}{}{0pt}{}{NH_2}{NH_2} + 2HCl.$$

When a solution of ammonium cyanate is evaporated on the water bath to dryness, it is transformed into urea, $NH_4CNO = CO(NH_2)_2$. In quantity urea may be prepared by heating anhydrous potassium ferrocyanide with potassium carbonate, when a mixture of potassium cyanate and cyanide is obtained; this mixture is then heated with red lead till all cyanide is oxidised to cyanate ($4KCN + Pb_3O_4 = 4KCNO + 3Pb$); the cyanate is now treated with ammonium sulphate solution, filtered from the potassium sulphate that separates, and evaporated to dryness on the water bath; the dry residue is repeatedly extracted with absolute alcohol; excess of alcohol is distilled off, and the rest allowed to stand till the urea crystallises out. To obtain urea from urine, the urine is evaporated to a syrupy consistency on the water bath; when cool, concentrated nitric acid is added—urea nitrate crystallises out. The nitrate is filtered off (through glass-wool), decomposed by warming with barium carbonate and water for several hours, filtered from excess of barium carbonate, and evaporated to dryness on the water bath; the mixture of barium nitrate and urea is separated by extraction with absolute alcohol as before.

Ureides (*Chem.*) Compounds formed by elimination of water between urea and an acid or aldehyde. Parabanic acid (*q.v.*) is a ureide; so are alloxan, alloxantin, uramil, etc.—all mentioned under Uric Acid (*q.v.*)

Ureter (*Zoology*). The urinary duct leading from the kidney to the bladder or to the cloaca.

Urethanes (*Chem.*) The esters of carbamic acid.

$$CO<^{NH_2}_{OH} \qquad CO<^{NH_2}_{OC_2H_5}$$

Carbamic acid (unknown). Ethyl carbamate (urethane).

Ethyl carbamate is a white crystalline solid; melts at 50°; boils at 184°; sublimes below its boiling point; easily soluble in water and in alcohol. It is easily hydrolysed by alkalis:

$$CO<^{NH_2}_{OC_2H_5} + 2HONa = CO<^{ONa}_{ONa} + NH_3 + C_2H_5OH$$

Heated with ammonia, it gives urea. Urethane is obtained by allowing ethyl carbonate (a colourless liquid obtained by the action of ethyl iodide on silver carbonate) to stand in contact with ammonia till it has all gone into solution, then evaporating *in vacuo*. If amines be used in place of ammonia, alkyl urethanes are obtained—*e.g.* with methylamine, methylurethane—

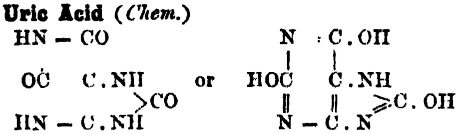
$$CO<^{NHCH_3}_{OC_2H_5}$$

is obtained; it is a colourless liquid. When an ethereal solution of methylurethane is kept cold and treated with nitrous fumes (from arsenious oxide and nitric acid), nitrosomethylurethane is formed:

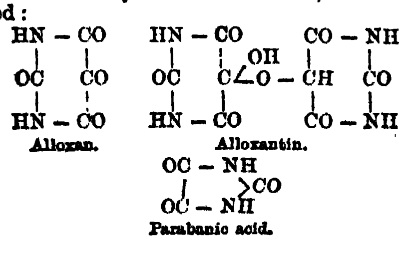
$$CO<^{N.NO.CH_3}_{OC_2H_5}.$$

It is washed with water, then with sodium carbonate solution, and dried over anhydrous sodium sulphate; its ethereal solution yields diazomethane (*q.v.*) when warmed with caustic potash in methyl alcohol solution.

Uric Acid (*Chem.*)

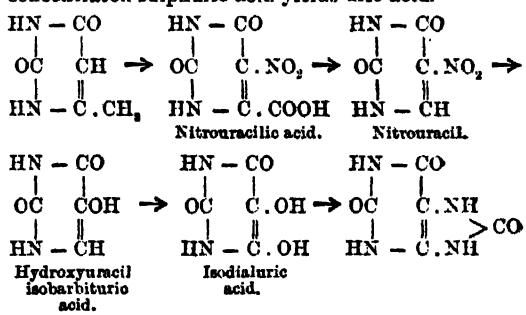


(2 : 6 : 8 trioxypurine. *See* PURINES.) A white crystalline powder when pure (rhombic plates); one part dissolves in about 16,000 parts of cold water or in 1,600 of boiling water; it is insoluble in the usual organic solvents (alcohol, ether, etc.), but is said to dissolve in warm glycerine. When heated it decomposes without melting, giving off a smell of burnt feathers, and forming ammonia, urea, cyanic and cyanuric acids. Uric acid reduces Fehling's solution. When carefully oxidised by nitric acid, uric acid gives alloxan and urea; further oxidation gives parabanic acid (*q.v.*); if the oxidation is effected by dilute nitric acid, alloxantin is formed:



Alloxan. Alloxantin. Parabanic acid.

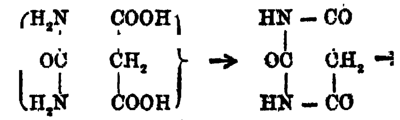
On adding ammonia to the residue obtained by evaporating uric acid with nitric acid on the water bath, murexide is formed. Murexide is the ammonium salt of purpuric acid (*q.v.*) This is an important test for uric acid. Uric acid is a weak dibasic acid, and forms three series of salts; *viz.* $C_5H_2M_2N_4O_3$ (normal salt); $C_5H_3MN_4O_3$ (biurate); $C_5H_3MN_4O_3 . C_5H_4N_4O_3$ (quadriurate), where M is a monovalent metal or base. The alkali urates are more soluble in water than uric acid itself, but the normal salts are resolved by much water into biurates. The urates of certain organic bases are also far more soluble in water than uric acid; *e.g.* piperazine (*q.v.*), which is used as a remedy (probably useless) in gout. Lithium biurate is very soluble in water—hence the use of lithium salts in gout, but their value as a remedy is doubtful. Uric acid is completely precipitated from its solutions by saturating the latter with ammonium chloride; the precipitate consists of ammonium biurate, which is quite insoluble in a saturated solution of ammonium chloride—basis of a method of estimating uric acid in urine. The acid occurs in urine—a healthy adult excretes from 0·2 to 1·25 grams in twenty-four hours; it is a common constituent of urinary calculi; in the blood of gouty persons it occurs as sodium biurate; it also occurs in the excreta of birds and serpents. Uric acid can be prepared from the excrement of serpents, hens, or pigeons by the following process: The material is dissolved in 5 per cent. caustic potash solution and boiled as long as ammonia escapes; a rapid stream of carbon dioxide is passed through the filtered solution till it is nearly neutral; the acid potassium urate thus precipitated is filtered, washed, dissolved in hot dilute caustic potash and poured into excess of hydrochloric acid. If the precipitated acid is still coloured, the process is repeated on it. Uric acid has been synthesised—(1) from methyl uracil (*see* ETHYLACETOACETATE), which is simultaneously oxidised and nitrated by nitric acid; the potassium salt of nitrouracilic acid loses carbon dioxide when boiled with water, and the resulting nitrouracil on reduction with tin and hydrochloric acid gives aminouracil and hydroxyuracil. Bromine water oxidises both these compounds to isodialuric acid, and the latter when heated with urea and concentrated sulphuric acid yields uric acid.



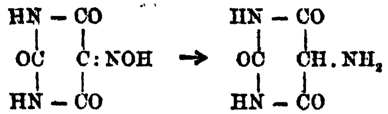
Nitrouracilic acid. Nitrouracil. Hydroxyuracil isobarbituric acid. Isodialuric acid.

(2) From malonic acid and urea, which condense under the influence of phosphorus oxychloride at 100° to the ureide of malonic acid (barbituric acid), which in solution is converted by potassium nitrite into isonitrosobarbituric acid (violuric acid)—a compound also formed by the action of hydroxylamine on alloxan. On reduction with hydriodic acid, violuric acid gives aminobarbituric acid (uramil), which on boiling with a solution of potassium cyanate gives pseudouric acid; the latter when added to melted

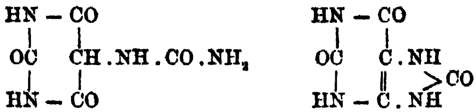
oxalic acid or when boiled with 20 per cent. hydrochloric acid gives uric acid:



Urea. Malonic acid. Barbituric acid.



Violuric acid. Uramil.



Pseudouric acid.

Uriconian Rocks (*Geol.*) A name given to certain Pre-Cambrian igneous rocks in the neighbourhood of the Wrekin. The name is derived from Uriconium, a Roman station. *See* PRE-CAMBRIAN ROCKS.

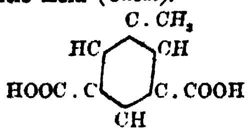
Urn (*Archæol.*) (1) A large kind of vase with an oviform or a rounded body standing on a foot; used as a receptacle for the ashes of the dead, as an electoral vase, etc. (2) A Roman liquid measure, equal to half the Amphora (*q.v.*)

Urticaceæ (*Botany*). A natural order of Dicotyledons, comprising the Nettles, and in some classifications the Mulberry and Elm. Many valuable fibres are obtained from plants of this order.

Ut (*Music*). The first of the sol-fa syllables. In England and many other countries *do* has been substituted for *ut* (*see* SOL-FA). *Ut bémol, C flat; ut dièse, C sharp.*

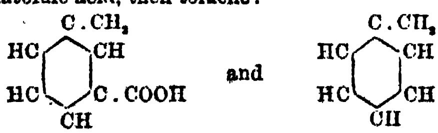
Uvic Acid (*Chem.*) *See* PYROTRITARIC ACID.

Uvitic Acid (*Chem*).

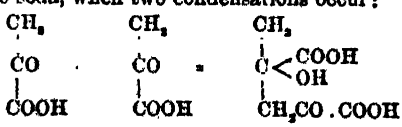


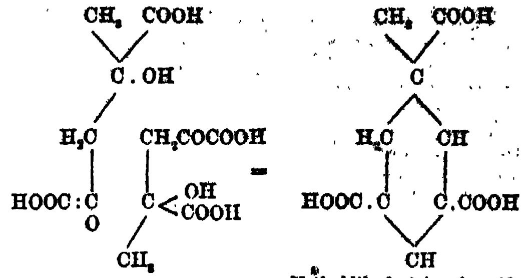
(Mesidic acid).

White needles; melts at 287°; soluble in alcohol and ether; when heated with quicklime it gives first metatoluic acid, then toluene:

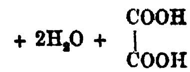


On oxidation with chromic acid it yields trimesic acid—the methyl group is oxidised to carboxyl (COOH). It is obtained by oxidising mesitylene (*q.v.*) with dilute nitric acid; it is also formed from pyruvic acid (*q.v.*) along with other acids by boiling with baryta water. The formation of uvitic acid from pyruvic acid is best effected by boiling with caustic soda, when two condensations occur:





Methyldihydrotrimesic acid.



Oxalic acid.

The methyldihydrotrimesic acid loses carbon dioxide and two atoms of hydrogen when added to hot concentrated sulphuric acid, and forms uvitic acid.

Uwarowite (*Min.*) A lime-chrome Garnet of emerald green colour from the Ural Mountains. *See* GARNET.

V (*Chem.*) The symbol for VANADIUM (*q.v.*)

V, v (*Phys., Eng., etc.*) A symbol for (1) Velocity, (2) Volume, (3) Potential Difference or Electromotive Force.

Vaccinium (*Botany*). A genus of the order *Ericaceæ*, represented in Britain by the Whortleberry, Cowberry, and Cranberry.

Vacuum. Theoretically, an empty space, containing no matter whatever. In practice, the term is applied to a space containing a small quantity of some gas at a very low pressure. The lowest pressure attained is less than the fifty-millionth part of an atmosphere.

Vacuum Brake (*Eng.*) A form of brake used on railway trains. The brake blocks are actuated by pistons working in exhausted cylinders, air being admitted on one side of the piston. The vacuum is produced by pumps on the locomotive. *See under* RAILWAYS.

Vacuum Gauge (*Eng.*) A gauge which measures the gaseous pressure in a partially exhausted space, or, more usually in the case of steam engines, the difference between the pressure of the atmosphere and that of the gas, etc., inside the space under consideration. This difference of pressure may be expressed in pounds per square inch, or in inches of mercury, just as the atmospheric pressure is.

Vacuum Pump. *See* AIR PUMP.

Vacuum Tube (*Phys.*) A tube containing a gas at a very low pressure (*i.e.* a so-called vacuum), usually fitted with electrodes by means of which the tube is connected to the secondary terminals of an induction coil. A very characteristic series of phenomena accompany the electric discharge which takes place through the tube, *e.g.* bands and striæ of light, and various forms of radiation, such as Cathode, Lennard, and Röntgen Rays. *See* RADIATION.

Vair. One of the heraldic "furs." It resembles a number of little shields placed in rows, the alternate ones reversed and of different tincture. The tinctures are argent and azure unless otherwise stated. *See* HERALDRY.

Valency (*Chem.*) (Quantivalence: Atomicity). The number of hydrogen atoms which can unite with one atom of an element A may be taken as one method of defining the valency of A. But some elements do not unite with hydrogen, and some others that do form compounds whose molecular weights are unknown. To meet this difficulty chlorine may be used to determine the valency of the element, as it is known that one atom of chlorine unites with one atom of hydrogen. Using one or other of these means we have—

MONOVALENT ELEMENTS (Monads):

H, ClH, BrH, FH, IH, $AgCl$, $InCl$.

DIVALENT ELEMENTS (Diads):

OH_2, SH_2, SeH_2, $ZnCl_2$, $HgCl_2$, $InCl_2$, $SnCl_2$, $PbCl_2$, $FeCl_2$, $CrCl_2$.

TRIVALENT ELEMENTS (Triads):

BH_3, NH_3, PH_3, AsH_3, SbH_3, $InCl_3$, $AlCl_3$, $BiCl_3$, $FeCl_3$, $CrCl_3$.

TETRAVALENT ELEMENTS (Tetrads):

CH_4, SiH_4, $SnCl_4$.

PENTAVALENT ELEMENTS (Pentrads):

PCl_5, WCl_5.

HEXAVALENT ELEMENT (Hexads):

WCl_6.

The compounds used in the above table to determine the valency of the elements are all gases or are capable of being gasified at a high temperature, so that all the above formulæ are correct either at the ordinary temperature or at a high temperature. It is seen at once that some elements have more than one valency, *e.g.* indium, tin, iron, chromium, phosphorus, tungsten. Again, while at moderately high temperatures the following compounds $SnCl_2$, $FeCl_2$, $CrCl_2$, $AlCl_3$, $FeCl_3$, and $CrCl_3$ (most probably) have the formulæ assigned to them, at lower temperatures they have a formula which is in all cases double the foregoing, *viz.* Sn_2Cl_4, etc., so that some elements alter their valency with the temperature. If this view be not taken, then it must be assumed that the simpler molecules in any one case unite with each other at lower temperatures, but are unable to do so at high temperatures; on this assumption the double molecules would be molecular compounds. In the above table the valency of sulphur, nitrogen, and lead are shown to be two, three, and two respectively. But the following compounds of these elements can all have their vapour densities determined, and are thus known to have the formulæ assigned to them:

SO_2, SO_3, SF_6, NH_4Cl, $Pb(CH_3)_4$;

and oxygen is divalent, fluorine, hydrogen, and chlorine monovalent, and the group CH_3 is methane (CH_4) less one hydrogen atom, and therefore also monovalent. Hence it must be concluded that sulphur may be divalent, tetravalent, or hexavalent; nitrogen trivalent or pentavalent, lead divalent or tetravalent. It is now seen that the valency of an element varies with the nature of the other element or elements with which it is united; and as sulphur trioxide breaks up on heating into the dioxide and oxygen the valency of this element changes with the temperature. In the case of the elements sodium, potassium, calcium, strontium, barium, compounds capable of being volatilised at temperatures suitable for vapour-density determination are not known (potassium iodide is an exception—in this compound potassium is monovalent), so that their valencies are decided from the results of analysis alone. For example, the result of analysis shows the composition of sodium chloride to be $NaCl$, but its true formula may be Na_2Cl_2 or Na_3Cl_3, etc. Now sodium is a metal of low melting point (96°) and chlorine is a gas, and it would seem unlikely that if sodium chloride had the formula $NaCl$ it would melt at a high temperature: for instance, silver melts at 961°, and silver chloride which has the formula $AgCl$ melts at 450°. In view of these facts sodium chloride, which melts at 815°, is more likely to have the formula Na_3Cl_3 which would make sodium trivalent

$$\begin{array}{c} ClNa \bigtriangledown NaCl \\ Na \\ | \\ Cl \end{array}$$

than $NaCl$. Thus it is seen that in the case of the important element sodium it is assumed rather than proved that it is a monovalent element, and a similar remark applies to all those metals which do not form vaporisable compounds. But it must be remarked that the sodium ion carries the same charge as a hydrogen ion, and so the ion is monovalent. In cases of this kind the Periodic System is of some service in determining valency—the metals of Group I. are monovalent or trivalent except in the case of copper, which is divalent. *See* PERIODIC SYSTEM. As another instance of the determination of valency in the case of non-vaporisable compounds, the case of tetravalent oxygen may be quoted. *See* OXONIUM COMPOUNDS. From the table it will be seen that nitrogen and carbon are respectively trivalent and tetravalent; but in the two compounds NO and CO these elements are almost certainly both divalent. To meet this difficulty these compounds may be called unsaturated: that is, the nitrogen and carbon are not acting in them with their highest valency, and they have therefore the power to unite with elements or groups sufficient to bring up their valency to three or five in the case of nitrogen and to four in the case of carbon. Now nitric oxide unites more readily with oxygen than with any other element, and we then get the compound NO_2, in which nitrogen is tetravalent; or it may be assumed that the compound N_2O_4 is formed first, in which the nitrogen is pentavalent, and that this breaks down with two molecules NO_2—that is, the valency of nitrogen changes from five to four. Carbon monoxide adds directly one atom of oxygen or two atoms of chlorine, and the carbon becomes tetravalent—CO_2 and $COCl_2$. In writing the formulæ for compounds, the valency of the elements concerned is generally represented by lines, every line attached to the symbol of an element representing its power to unite with one monovalent element or group. For example, $O=C=O$ means that carbon and oxygen are united together in such a way that one tetravalent carbon atom is united to two divalent oxygen atoms. Again,

$$\begin{array}{c} H-C-H \\ \| \\ H-C-H \end{array}$$

represents two tetravalent carbon atoms each united with only two monovalent hydrogen atoms and a divalent group $=CH_2$. In this latter case each carbon atom can unite with one monovalent atom or group and so become "saturated."

$$\begin{array}{c} H-C-H \\ \| \\ H-C-H \\ \text{Ethylene.} \end{array} + Cl_2 = \begin{array}{c} Cl \\ | \\ H-C-H \\ | \\ H-C-H \\ | \\ Cl \end{array}$$

The two lines between the two carbon atoms in ethylene are not intended to mean anything more than this. Two carbon atoms joined in this way are said to be "doubly linked." Similarly, in acetylene

$$\begin{array}{c} CH \\ ||| \\ CH \end{array}$$

the two carbon atoms are "trebly linked," meaning only that each carbon atom can unite with two suitably chosen monovalent atoms or groups, or their equivalents, as two hydrogen atoms and one oxygen atom

$$\begin{array}{c} CH \\ ||| \\ CH \end{array} + H_2O = \begin{array}{c} CH_3 \\ | \\ CHO \end{array}.$$

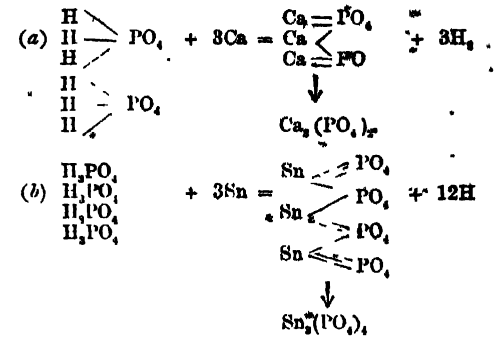
See UNSATURATED COMPOUNDS. There are many compounds whose existence seems to be incapable of explanation on the ordinary theory of valency: such are salts containing water of crystallisation—*e.g.* $CaCl_2 6H_2O$, and the complex compounds of salts of metals like cobalt and platinum with ammonia. Accordingly, it has been assumed that these are "molecular compounds"; that is, the molecules composing them are endowed with the property of uniting with each other just as the atoms of elements are, only there are no rules as to the valency of these molecules. Notwithstanding the inadequacy of the theory of Valency, it has rendered, and still renders, invaluable service to Chemistry. This arises from two causes. First, it is easily and accurately applied to exhibiting the constitution of salts, acids, and bases; and also the monovalent atoms and groups in these classes of compounds are those which in solution carry a charge of electricity equal to that carried by the hydrogen ion, while the divalent elements and groups carry twice that charge, and so on. Secondly, the valency of carbon is remarkably constant, probably owing to its electrically neutral character—it forms, in Series 1 of the Periodic System (*q.v.*), the border element, as it were, between the electropositive elements of Groups I., II., and III., and the electronegative elements of Groups V., VI., and VII. This constancy in the valency of carbon has contributed more than anything else to the development of Organic Chemistry. As to the nature of valency nothing is certainly known. For a valuable extension of the theory of valency, *see* WERNER'S THEORY. Two examples of the application of valency to the determination of formulæ are appended. (1) The formula for sulphur dioxide is SO_2. This may be written $O=S=O$. This gas unites, molecule for molecule, with chlorine, forming a stable compound, sulphuryl chloride, which will have the formula

$$O=\overset{\displaystyle Cl}{\underset{\displaystyle Cl}{\overset{|}{\underset{|}{S}}}}=O,$$

for the grouping —O—Cl would be unstable (Hypochlorite group). Sulphuryl chloride reacts with water in the proportion of one molecule of the former to two of the latter, giving sulphuric and hydrochloric acids: the only feasible way of representing this reaction is

$$O=\overset{\displaystyle Cl}{\underset{\displaystyle Cl}{\overset{|}{\underset{|}{S}}}}=O + \begin{array}{c} HOH \\ \\ HOH \end{array} = O=\overset{\displaystyle OH}{\underset{\displaystyle OH}{\overset{|}{\underset{|}{S}}}}=O + 2HCl,$$

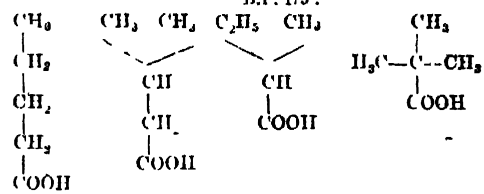
thus giving the constitution of sulphuric acid. (2) The formula for phosphoric acid being H_3PO_4, what will be the formula for calcium phosphate and stannic phosphate? Calcium is divalent, and tin in the stannic salts tetravalent, so we must have:



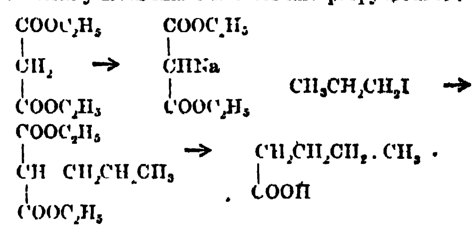
Valentenite (*Min.*) The orthorhombic antimonic oxide Sb_2O_4 (*cf.* SENARMONTITE). Antimony = 84·3, oxygen 15·7 per cent; often in acicular crystals of a white or greyish colour, with high lustre. It is an alteration product of other antimony ores, and occurs with them at numerous mines in Bohemia, Saxony, etc.

Valeric Acids (*Chem.*) $C_5H_{10}O_2$ (Valerianic acids). There are four of these acids:

I. Normal valeric acid B.P. 186°.	II. Isovaleric acid. B.P. 174°.	III. Methylethyl-acetic acid (contains an asymmetric carbon atom). B.P. 175°.	IV. Trimethyl-acetic acid. M.P. 35°, B.P. 163°.



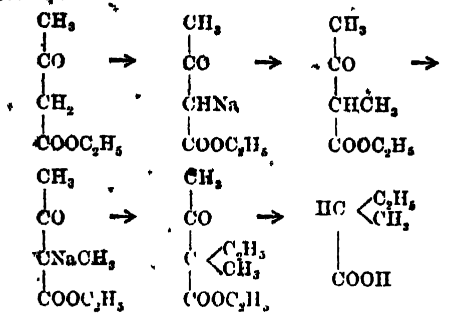
I. A colourless liquid; sparingly soluble in water; smells like butyric acid. It can be obtained synthetically from malonic ester and propyl iodide:



II. A colourless liquid; sparingly soluble in water; it has a disagreeable smell of old cheese: it is oxidised by chromic acid to acetic acid and carbon dioxide. It occurs in valerian root as bornyl ester, in the wild guelder rose and a number of other plants, as a decomposition product of proteids, and in perspiration. It is obtained, but not free from III., by oxidising amyl alcohol with potassium dichromate and sulphuric acid; a pure preparation can be obtained from malonic acid and isopropyl iodide (*cf.* I.) Its isoamyl ester smells of apples, and is used as a flavouring agent.

III. A colourless liquid; smells like II.; on oxidation it gives carbon dioxide and acetic acid. It is

known in all three forms (dextro-, lævo-, and inactive); the lævo-acid is obtained when amyl alcohol is oxidised. Synthetically it can be obtained either from ethyl malonate or ethyl acetoacetate:



The inactive acid so obtained can be resolved by brucine, the lævo-salt being the less soluble. The acid occurs in angelica oil, which is used in flavouring liqueurs.

IV. A white solid; sparingly soluble in water; smells like II. and also like acetic acid. It is prepared from tertiary butyl alcohol by converting it into the iodide, the iodide to nitrile, and hydrolysing the latter. *See also* STEREOCHEMISTRY.

Valley (*Build.*) The V-shaped hollow between two intersecting roof surfaces.

Valonia (*Botany*). The commercial name given to the unripe acorns of *Quercus Ægilops* (ordo., *Cupuliferæ*), used in tanning, and obtained from an oak grown in the Levant.

Valve (*Eng.*) A device for closing a pipe or passage in order to control, or entirely stop, the flow of a liquid or gas. *See* SLIDE VALVE, BALL VALVE, *etc.*

Valve Box, Chest, Casing, etc. (*Eng.*) The case or cover of a valve.

Valve Closet (*Sanitation*). This consists of a basin, with a circular outlet at its lowest part, closed by a watertight valve. This valve is hinged at one side and connected with the handle of the closet, so that when the handle is raised the valve is depressed into a metal box which is connected by means of a siphon or anti-D-trap with the soil pipe. A valve closet should not be flushed from a water-waste preventer, but from a small cistern holding from 6 to 8 gallons of water, so as to provide an "after flush," that is, a supply of water to remain in the basin. To secure this after flush it is usual to employ what is known as a "bellows regulator," a piston moving in a cylinder and connected with the handle of the closet and the valve of the supply pipe. The cylinder is provided with an air escape pipe, fitted with a tap, which regulates the rate at which the piston descends, and thus determines the amount of the after flush. When the handle is lifted the piston is raised, and the valve in the supply pipe is opened; but when the handle is released the water continues to flow until the piston falls and closes the valve. An overflow pipe, trapped, should also be provided to the basin, and to prevent siphonage this should be connected with the supply pipe by a branch pipe, so that the water is renewed every time the closet is used. It is also advisable to attach a ventilating or "puff" pipe to the valve box, so that when the handle is raised the foul air may escape into the open air instead of into the apartment.

Valve Diagram. A diagram showing the exact position of a slide valve, and consequently the opening of the ports of the engine, at any position of the stroke. There are several forms, due to REULEAUX, ZEUNER, etc., but they all aim at giving geometrical representation of the same facts.

Valve, Electric (*Elect. Eng.*) (1) Any mechanical valve operated by electrical means. (2) More usually, any conducting arrangement which permits a current to flow in one direction only, and which may therefore be used to rectify an alternating current. It may take various forms: *e.g.* a particular kind of electrolytic cell, or a suitably designed vacuum tube.

Valve Face (*Eng.*) The surface on which a valve rests or moves: applied especially to the surface on which a slide valve (*q.v.*) works.

Valve Gear (*Eng.*) The mechanism which moves the slide valve (or its equivalent) in an engine. *See* LINK MOTION.

Valve Rod (*Eng.*) A rod, one end of which is fixed to a valve, the other end passing out through a suitable stuffing box, and being acted upon by some form of valve gear.

Valve Seat (*Eng.*) The surface on which a valve rests: applied to disc, ball, and other forms of valve other than a slide valve.

Valve Sector (*Eng.*) The slotted link in the Link Motion (*q.v.*)

Valve Spindle (*Eng.*) (1) The rod by which a valve is moved. (2) The short rod (used in many disc valves, etc.) which guides the motion of a valve as it rises and falls.

Valve Spring (*Eng.*) A spring used to keep a valve in place, *i.e.* in contact with its seat, when it is not required to be open. Springs are commonly fitted to the disc valves used in many forms of petrol engines (*q.v.*)

Vamping (*Leather Manufac.*) An over swelling of the skin during the liming or drenching, sometimes termed "blowing."

—— (*Music*). Playing an extemporised accompaniment to a solo.

Vanadinite (*Min.*) A vanadate and chloride of lead, $3Pb_3V_2O_8 \cdot PbCl_2$. Hexagonal and isomorphous with Kampylite (*q.v.*) It is usually in short prisms or globular masses of a yellow or greenish colour. From Wanlockhead in Dumfriesshire, Siberia, Mexico, etc.

Vanadium (*Chem.*) V. Atomic weight, 51·2. A rare element coming between phosphorus and arsenic in Group V. of the Periodic System. In its physical properties it resembles a metal; but its chemical properties are those of a non-metal. It is obtained by reducing the dichloride in hydrogen at a bright red heat: oxygen, nitrogen, and water vapour must be rigidly excluded from the apparatus. So prepared, it is a crystalline greyish white powder; melts at 1,680°; specific gravity, 5·5; burns to the pentoxide when heated strongly in oxygen; heated in nitrogen it forms the nitride VN; heated in chlorine it forms the tetrachloride VCl_4; hot concentrated sulphuric acid oxidises it; nitric acid of any strength oxidises it. The element is widely distributed, but always in small amount; apparently it always occurs in the form of vanadates. Thus

vanadinite is $3Pb_3(VO_4)_2 . PbCl_2$, isomorphous with apatite, pyromorphite, minietisite (*see these*); mottramite, found in the Keuper (*q.v.*), in Cheshire, is $(Pb, Cu)_3(VO_4)_2 . 2(Pb, Cu)(OH)_2$. Five oxides are known—namely, V_2O to V_2O_5. None of them forms salts of the form V_mR_n, where R is the acid radical; but oxysalts such as hypovanadic sulphate, $V_2O_2(SO_4)_2$, a greenish blue powder, and vanadyl sulphate, $V_2O_2(SO_4)_3$, red crystals, are obtained—the first by dissolving the tetroxide in sulphuric acid and heating, and the second by dissolving the pentoxide in hot dilute (1:1) sulphuric acid. The most important oxide is the pentoxide, V_2O_5, which is obtained from mottramite by extracting the crushed sandstone which contains the mineral with hydrochloric acid and concentrating the acid solutions and washings, adding ammonium chloride and evaporating again till ammonium metavanadate crystallises out. This salt is repeatedly crystallised and finally heated—the pentoxide remains. To purify it, it is again converted into ammonium vanadate, and the latter decomposed by heat. It forms yellowish red prisms; melts without decomposition; sparingly soluble in water; with alkalis it forms vanadates—*e.g.* ammonia gives ammonium metavanadate, NH_4VO_3. The tetroxide, V_2O_4, is a blue crystalline powder, obtained by prolonged exposure of the trioxide to air; insoluble in water. The trioxide, V_2O_3, is a black powder, obtained by heating the pentoxide in hydrogen. The dioxide, V_2O_2, is a lustrous grey powder, obtained by passing the vapour of the oxytrichloride with excess of hydrogen through a red hot tube filled with charcoal; insoluble in water; soluble in acids, giving a lavender solution which readily absorbs oxygen and has strong bleaching properties. The existence of the monoxide is not established beyond all doubt. The VANADATES are derived from the pentoxide. No orthovanadic acid, H_3VO_4, is known; but metavanadic acid, HVO_3, forms golden yellow scales slightly soluble in water. It is obtained by adding excess of ammonium chloride to a solution of copper sulphate, then ammonium metavanadate (*see above*), till a precipitate is obtained; the whole is warmed to 75°, and the product is washed with dilute sulphuric acid, sulphurous acid, and water, and dried at 100°. It is used as a pigment under the name "vanadium bronze"; pyrovanadic acid, $H_4V_2O_7$, is also known. Hypovanadates are derived from the tetroxide; thus potassium hypovanadate, $K_2V_4O_9 7H_2O = K_2O . 2V_2O_4 7H_2O$, forms red-brown scales very soluble in water; it is obtained by adding excess of caustic potash to a concentrated solution of hypovanadic sulphate (*see above*). CHLORIDES: Tetrachloride, VCl_4, is a dark brownish red liquid; boils with partial decomposition to trichloride and chlorine at 154°; fumes in air; dissolves in water, forming a blue solution of hypovanadic chloride, $V_2O_2Cl_4$; it is obtained by passing the vapour of the oxytrichloride with excess of chlorine over pure charcoal heated to low redness. The trichloride, VCl_3, forms shining peach-blossom coloured tables similar to chromic chloride; it is deliquescent, and dissolves in water with a brown colour; soluble in alcohol, forming a greenish blue solution, and in ether forming a green solution; heated in air it forms the pentoxide; it is obtained by heating the tetrachloride or by heating the trisulphide in a current of chlorine and separating it from the sulphur chloride, which is also formed, by fractional distillation. The dichloride, VCl_2, forms apple-green lustrous hexagonal plates; it is deliquescent; soluble in alcohol and ether like the preceding compounds; reduced in hydrogen it yields the metal; it is obtained by passing the vapour of the tetrachloride mixed with pure hydrogen through a glass tube heated to low redness. The oxytrichloride, $VOCl_3$, is a yellow liquid; boils at 127°; vapour density normal; emits red fumes in air and is decomposed by water, forming pyrovanadic (?) and hydrochloric acids; it is obtained by heating a mixture of the pentoxide with charcoal in chlorine and redistilling the product over sodium in a current of carbon dioxide. Three sulphides are known—V_2S_2; V_2S_3; V_2S_5. The trisulphide forms shining black leaves, and is obtained by heating the trioxide in sulphuretted hydrogen or pentoxide in vapour of carbon disulphide. The other sulphides are obtained from the trisulphide by heating it in hydrogen and with sulphur respectively.

Van der Waals' Equation (*Phys.*) The equation which expresses the relation of the pressure (p), volume (v), and absolute temperature (θ) for a perfect gas—

$$pv = R\theta$$

is only approximately true for any known gas. A more complete representation is given by the Equation of Van der Waals—

$$\left(p + \frac{a}{v^2}\right)(v - b) = R\theta$$

in which a and b are two additional constants depending upon the particular gas.

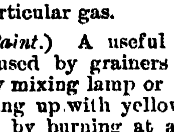
Vandyke Brown (*Paint.*) A useful pigment of a rich brown colour used by grainers and house painters, and made by mixing lamp or other black with red oxide and toning up with yellow ochre. A better quality is made by burning at a light heat cork cuttings, bark, etc. Vandyke brown is permanent, and works equally well in water, turpentine, and oil.

Vane (*Eng.*) A plate, arm, blade, or other device projecting from an axis for the purpose of being acted on by a moving current of air, water, etc., as in the case of a water wheel, turbine, windmill, etc.

——, **Wind** (*Meteorol.*) An arrow, or equivalent object, placed on a vertical support and free to turn horizontally. The direction the arrow points is the compass direction from which the wind is blowing.

Vanilla (*Botany*). The unripe fruit (Vanilla Bean) of the Mexican orchid *Vanilla planifolia* (order, *Orchidaceæ*) are dried, and afterwards treated with oil to retain the fragrance. An extract obtained from the bean is used for flavouring ices, confectionery, etc. Other tropical species, *e.g. V. grandiflora* and *V. aromatica*, are also employed, but are not equal in quality.

Vanillin (*Chem.*)

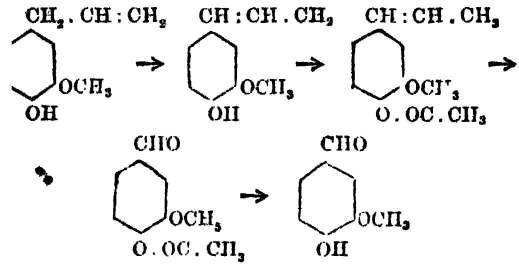


White needles; melts at 81·5°; boils at 285° (170° under a pressure of 15 mm. mercury); sublimes on heating; soluble in alcohol, ether, chloroform, hot petroleum ether, but slightly soluble in cold petroleum ether. The smell of vanilla is due to this substance, and vanilla pods contain about 2 per cent. of it; it is also found, but to a less extent, in gum benzoin from Siam and Sumatra. It is extensively used for flavouring confectionery and liqueurs. As an aldehyde it is easily oxidised to the corresponding

acid, vanillic acid, *e.g.* by moist air or by ammoniacal silver; sodium amalgam reduces it to vanillic alcohol and to hydrovanilloin

$$C_6H_3\left\langle\begin{array}{l}OH\\ OCH_3\\ CHOH\end{array}\right. . \left.\begin{array}{r}HO\\ H_3CO\\ CHOH\end{array}\right\rangle C_6H_3:$$

it yields an oxime and combines with sodium hydrogen sulphite. As a phenol it gives a colour reaction—blue—with ferric chloride; it gives an acetyl derivative with acetic anhydride. As an ether it splits off methyl chloride when heated in sealed tubes with hydrochloric acid. It can be extracted from vanilla pods, but is now made artificially in a variety of ways. (1) The glucoside coniferin occurs in the juice of the cambium of fir trees, and may be obtained by boiling the juice, filtering, and evaporating till the glucoside will crystallise out; the coniferin is then oxidised by rather dilute chromic acid, yielding a glucoside of vanillin, which, on hydrolysis by dilute sulphuric acid, yields glucose and vanillin, and the vanillin is extracted with ether. (2) Eugenol (*q.v.*) is converted into isoeugenol by boiling it with caustic potash in amyl alcohol for about twenty-four hours, distilling in steam to remove the alcohol, and liberating the isoeugenol with an acid; the isoeugenol is acetylated with acetic anhydride, oxidised with potassium permanganate in acetic acid solution, and the oxidation product hydrolysed by caustic potash; the vanillin is extracted with ether and purified by means of its sodium hydrogen sulphite compound:



Compare PIPERONAL. (3) From protocatechuic aldehyde (from catechol (*q.v.*) by Reimer's reaction (*q.v.*) by shaking with dimethylsulphate (Patented). (4) From guaiacol. *See* REIMER'S REACTION. There are several other ways of obtaining Vanillin.

Vanishing Point (*Painting and Drawing*). The point at which all the imaginary lines in the perspective of a picture or drawing converge: the intersection with the picture plane of a line or plane passing through the eye and parallel with the original line or plane, *i.e.* one in nature, etc.

Vapour *and* **Vapour Pressure** (*Phys.*) A vapour is best defined as a gas which can be condensed to a liquid by the application of pressure alone, without the necessity for lowering the temperature.

The actual gaseous pressure exerted by a vapour is termed the VAPOUR PRESSURE or VAPOUR TENSION. If the vapour be in contact with its liquid, this pressure attains a certain value, which depends only upon the temperature, and is termed the MAXIMUM VAPOUR PRESSURE, or SATURATION PRESSURE, and the vapour is said to be a SATURATED VAPOUR. If the space containing the vapour be diminished, some of the vapour will, in general, condense to a liquid, the pressure remaining constant; while an increase in the volume of this space is followed by additional evaporation which restores the pressure to its original value, so long as any of the liquid remains. When the liquid has entirely evaporated into the space, and the volume is increased, the vapour behaves to a great extent in a similar manner to a gas, *i.e.* the pressure falls. The vapour is now said to be UNSATURATED. The pressure may be increased if the supply of heat be further continued; the vapour rises in temperature, and is said to be SUPERHEATED.

So long as the space above a liquid is not saturated, vapour is continually given off, *i.e.* slow EVAPORATION occurs. If the liquid be heated, the vapour pressure rises and evaporation becomes more rapid. When the temperature has been raised sufficiently, the vapour pressure becomes at length equal to the superincumbent pressure, and bubbles of vapour are formed within the mass of the liquid itself. These bubbles rise to the surface and break, *i.e.* BOILING, or EBULLITION occurs.

The quantity of heat necessary to change unit mass of a liquid at any temperature into vapour at the same temperature is termed the LATENT HEAT OF VAPORISATION. This quantity varies with the temperature: for water, the value of the latent heat L, at a temperature t°C., is given by E. H. Griffiths as

$$L_t = 596{\cdot}73 - {\cdot}601\,t.$$

Vapour Pressure.—The pressure of a vapour may be measured in various ways. (1) Some of the liquid is introduced into the space above the mercury in a barometer tube and the consequent depression of the mercury is measured. (2) The boiling point of the liquid is observed at a known temperature.

Vapour Density.—There are several methods by which the density of a vapour may be determined. (1) DUMAS' METHOD consists in observing the mass of vapour which fills a bulb or globe of known volume at a known pressure and temperature. (2) VICTOR MEYER'S METHOD consists in observing the amount of air displaced from a vessel by the conversion into vapour of a small known quantity of the substance in a liquid form. The vessel is kept at a temperature above the boiling point of the liquid. (3) HOFMANN'S (*or* GAY-LUSSAC'S) METHOD depends upon the introduction of a known mass of the liquid into the space above the mercury in a barometer tube, as in the first method described under Vapour Pressure above.

Vargueno (*Furniture*). A seventeenth century Spanish cabinet serving the purpose of a secretaire, the body being box shaped and the front hinged at the bottom.

Variable Stars (*Astron.*) Stars which appear of different brightnesses or magnitudes at different times. Some are periodic, others are not. The periodic are divided into regular and irregular variables.

Variable Travel (*Eng.*) The travel, or distance moved through by a slide valve, can be altered at will in many forms of valve gear; *e.g.* with the ordinary link motion the travel can be varied from nothing up to the full "throw" of the eccentric by altering the position of the link. *See* LINK MOTION.

Variegated Yarn (*Textile Manufac.*) Fancy yarn composed of several colours, and the colours following in successive lengths. May be made on the spinning frame or the twisting frame.

Varnish (*Dec.*) Varnish is a liquid employed for improving the appearance and durability of a surface. On drying hard it usually has a lustrous shining coat, which resists the action of the air and moisture. Varishes are used in many trades, particularly by house and coach painters. They may be divided into two classes, SPIRIT VARNISHES and OIL VARNISHES. The former consist of a resin such as shellac, dissolved in alcohol, and become hard by evaporation of the spirit; they are not suitable for exposure to the weather. *Oil varnishes* are prepared from various gum resins, linseed oil, and turpentine. These are raised to a considerable heat in order to cause the gums to dissolve. The turpentine (*q.v.*) is added in order to "thin" the mixture and render it fit for application by a brush. The oil used in varnish making is almost invariably linseed oil (*q.v.*), but of late Chinese tung or wood oil has been successfully employed to a limited extent. The quality of varnish when properly made depends principally upon the gum resins used. The chief of these are animi, amber, benzoin, copal, dammar, clemi, kauri, mastic resin, sandarach, shellac, and thus (*q.v.*)

MANUFACTURE.—The process of making varnish, while comparatively simple, requires considerable practical experience in order to vary the operations according to the gums that are dealt with. It may be briefly explained thus: The gum resin is first sorted, cleaned, and crushed, and is then placed in the varnish pot or kettle, which fits in a circular hole in the floor of the melting chamber, under which is the fire pit. In most modern factories the pots are fitted with conical covers fixed to iron pipes, which communicate with a condensing apparatus where the fumes are got rid of. In the cover is a small hole through which a rod is placed, and this enables the operator to stir up the gum from time to time, and to ascertain when it is all melted. The temperature during the melting is from 500° to 650° F. When the gum is all melted—and this can readily be ascertained by an experienced operator—the lid of the pot is raised by means of a chain provided for the purpose, the pot is lifted on to a carrier and wheeled to the varnish room, where boiling linseed oil previously prepared is added to it, and the mixture is then cooked. The proportion of the oil and gum, as well as the degree of heat, vary considerably according to the grade of varnish that is being made. 500° F. may be taken as an average heat for ordinary varnishes of the best grade. Generally the more oil that is added the longer will the boiling take. It is seldom less than two hours, and may last for eight or ten. In the latter case a stout varnish will be the result, and an increased quantity of turpentine will be required to thin it to the right consistency. To ascertain when the oil and melted gum have completely combined, the stirrer is withdrawn from time to time and a drop of the varnish is allowed to fall on to glass, when it immediately cools and has a cloudy appearance if the materials are not fully incorporated. The varnish being now made, the pot is withdrawn and allowed to cool, either in the open air or an open building prepared for the purpose. The turpentine is then added and stirred in. The final process is to clarify the varnish. This is usually effected by simply storing it in tanks for a few months, and then pumping it to other tanks for the purpose of giving it those peculiar qualities which come only from age, new varnish being almost invariably most unsatisfactory. The best varnishes are often stored for several years, and it is important that an absolutely uniform temperature be maintained the year round.

COLOUR.—In some varnishes a very light colour is necessary, as for example those which are intended for use over white work, maple, etc. In others colouring matter is added such as dragon's blood, gamboge, annatto, turmeric, saffron, indigo, and certain of the aniline dyes.

GRADES.—Varnishes are made in a great variety of grades for different purposes, and although many house painters sometimes mix different grades together, the practice is to be strongly deprecated. The following are the names of some of the varnishes in common use: Hard carriage varnish, coating body, hard church oak, finishing body, elastic carriage, pale copal, crystal, mastic, white hard, violin varnish, Brunswick black, Berlin black, etc. There is also a variety of varnish termed FLATTING VARNISH, which dries without gloss, and is used with good effect to form a contrast with an adjacent lustrous surface, *e.g.* the stiles and rails of a door may be varnished in the ordinary manner, and the panels be flatted.

DEFECTS.—Many of the defects in newly varnished work may be attributed to conditions, changes in the temperature, or a humid atmosphere during the time the varnish is being applied. Thus a hall newly varnished will sometimes be found to be clouded on one side due to the door being opened and a current of cold air being admitted whilst the varnishing was being proceeded with. A well ventilated room, rather warm, kept at a uniform temperature with freedom from dust in the air, affords the best conditions for successful varnishing.—A. S. J.

Varnish (*Photo.*) A solution of resinous substances applied to the film of a negative to protect it from contact with the free silver nitrate in silver printing, and to resist the action of air and moisture.

Vascular Bundle (*Botany*). The term given to the longitudinal strands of the stem, root, and leaf. A bundle consists of conducting tissues (soft bast and wood) and in some cases of a formative tissue, cambium, in addition. *Cf.* CELL.

Vase. A symmetrical hollow vessel, decorative in character, generally high in proportion to its width, furnished with a foot, and either with or without handles. Vases are generally made of some kind of pottery, but sometimes of glass, metal, stone, or other material. Ancient Greek vases were used for the purposes of everyday life, and the subject or *motif* of the decoration was often a domestic scene, so that the study of this form of art has shed much light on various phases of the life of ancient Greece. The following are the chief characteristics of Greek vases dating from the seventh to the third century B.C.—(1) Early or Athenian Dipylon style: geometrical ornament and grotesque figures. (2) Corinthian style: Oriental in character and consisting of bands or zones of animals, real and fabulous, and foliage, with figured borders, painted generally in black or dull red, sometimes in violet. (3) Black figure style: the decoration is generally black, the figures being silhouettes drawn on the natural ground; certain details sometimes added in other colours. (4) Red figure style: red figures on a black ground characterise the Periclean age, the finest period of Greek art. The oldest surviving example of artistic vase is probably that numbered 22,559 in the 4th Egyptian Room at the British Museum. It is inscribed with the name of Meren-Rā (B.C. 3233). One of the most famous

examples is the Portland Vase, a glass cinerary urn found near Rome, in the so-called tomb of Alexander Severus, and now in the Gold Room at the British Museum. Scenes from the legend of Peleus and Thetis form the subject of the decoration, which is cut in cameo. (*See under* GLASS MANUFACTURE.) Among other famous examples may be mentioned a specimen of Chinese porcelain of the Ta Ming dynasty (A.D. 1426) in the Salting Collection, South Kensington; and "El Jarro," a winged vase of Hispano-Moresque origin, decorated with gold lustre arabesques, the ground being blue and white (in the Museum of the Alhambra). *See* AMPHORA, CALPIS, CANTHARUS, CRATER, CYLIX, CYATHUS, ŒNOCHOË, OXYBAPHON, PROCHOOS, STAMNOS, URN, POTTERY AND PORCELAIN.

Vaseline. A gelatinous, translucent, unctuous body derived from crude petroleum, and popularly known as petroleum jelly. It is prepared by subjecting a selected quality of crude petroleum to dry heat in iron vessels until the lighter portions are driven off in vapour, and there remains the heavier portions of oil in a highly concentrated state. After repeated filtering through bone black, vaseline is obtained in the form of a solid jelly which is odourless and of a white opal colour. It is perfectly neutral, and entirely free from taste. Three varieties are on the market, known respectively as "white," "blonde," and "red." White vaseline is used for internal administration, for external applications of a delicate nature, and other refined toilet purposes. It is also successfully employed as the vehicle for several caustic, disagreeable, and nauseating medicines such as quinine, iodine, chloral, etc. Vaseline is the base of many toilet preparations and ophthalmic pomades and salves, and it is most useful to surgeons. The blonde variety is most generally met with, and is used for all sorts of wounds, burns, bruises, etc. Red vaseline is employed for ordinary pharmaceutical ointments, for veterinary purposes, for preserving leather, etc. The word "vaseline" is the property of the Chesebrough Manufacturing Company, and in this country can only be lawfully applied to their preparations.

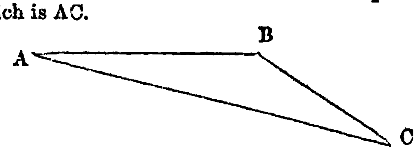
—— (*Chem.*) A semi-solid mixture of hydrocarbons chiefly of the paraffin series; melts at 35° to 50°; insoluble in water, sparingly soluble in alcohol, readily soluble in ether, benzene, chloroform. It is obtained from crude petroleum by distilling the lower boiling portions first, then further distilling under reduced pressure, heating by steam. The residue is then filtered through animal charcoal; the first portions of the filtrate form the colourless vaseline, the later portions are coloured yellowish brown with green fluorescence. Vaseline is employed as a lubricant, and in medicine in the preparation of some ointments.

Vat (*Paper Manufac.*) The wooden tank containing beaten pulp from which handmade sheets of paper are prepared.

Vatoe (*Silk Manufac.*) A sort of reed used by the turner-on in the process of beaming, to place the warp in its due order on the cane roll.

Vault (*Architect.*) (1) An arched ceiling or covering to a building or part of a building, usually constructed of brick or stone but sometimes of wood. (2) A subterranean apartment, whether arched or not. *See* BARREL VAULT, GROINED VAULT, RIB AND PANEL VAULT, *and* FAN VAULT.

Vectors (*Phys.*) A vector is a quantity which has direction as well as magnitude, *e.g.* Displacement, Velocity, Mechanical Force, Electric and Magnetic Force, Electric Current. To specify any such vector it is necessary to know (1) its numerical magnitude, size, or TENSOR, as this is sometimes termed, and (2) its direction or ORT, *i.e.* the angle which it makes with some specified or arbitrary line. The ADDITION OF VECTORS is not the simple addition of their numerical values; let a vessel sail a distance represented in magnitude and direction by AB, and from B a distance represented by BC; these two lines represent displacements, which are vectors, and the sum of those vectors is the resultant displacement, which is AC.



A further example of the addition of vectors is given in the process of finding the resultant of a number of forces (*see* GRAPHIC STATICS, *p.* 268). The theorems of the Parallelogram of Forces, Polygon of Forces, etc., are cases of the addition of vectors. The MULTIPLICATION OF VECTORS is of much importance. The SCALAR PRODUCT of two vectors is the product of their numerical values into the cosine of the angle between them. For example, if a force F act on a body which is displaced through a distance x at an angle θ with the direction of the force, the work done is equal to the scalar product of the two vectors F and n, *i.e.* to $Fs \cos\theta$. This quantity has no direction, *i.e.* it is not a vector, but a scalar quantity. The VECTOR PRODUCT of two vectors is a third vector at right angles to the plane containing the first two, and its magnitude is equal to the product of the numerical values of the first two, into the *sine* of the angle between them. The vector product is important in the theory of electricity, *e.g.* the force on a conductor carrying a current and placed in a magnetic field is a vector product. If the current be 5 absolute units, and the conductor carrying it be placed in a field of 1000 lines per square centimetre, so that it makes an angle of 60° with the direction of the lines of force, the mechanical force on the conductor is $5 \times 1000 \times \sin 60°$ dynes per unit length.

V Edges *or* **Vee Edges** (*Eng.*) When one part of a machine has to slide or move in a straight line over another part, it is usual to provide the fixed part with projecting edges whose cross section is of the form of the letter V. The moving portion is then formed with slots or grooves of corresponding shape, which fit the fixed edges or strips. The bed of a lathe, or the slides of a slide rest, are examples. In certain other cases the fixed V edges may be on the moving part, the grooves being then formed on the fixed portion. This is usually the case in large planing machines.

Vegetable Black (*Dec.*) A very light weight but intensely black pigment, consisting almost wholly of pure carbon. It is made at the same time as lamp black (*q.v.*), being selected from that part of the stove which is farthest away from the furnace in which various refuse oils, etc., are burned. Vegetable black is largely used in the manufacture of the finest printers' inks, black varnishes, and by decorators in their finest work.

Vegetable Ivory. *See* COROZO NUT.

Vegetable Oils. *See* OILS *and* LUBRICANTS.

Vegetable Tallow. A fat obtained from the seeds of the Chinese tallow tree (*Stillingia sebifera*). It is used to a limited extent in candle making, and has a specific gravity of 0·915, and melts at 43—46° C.

Vegetable Wax. *See* CARNAÜBA WAX.

Vehicle (*Paint.*) The medium or liquid with which pigments are mixed in order that they may be applied to a surface. *See* PAINTING *and* HOUSE PAINTING.

Veil (*Cost.*) A piece of fabric generally of light texture, worn over the face or head for protection or ornament; in the middle ages a circular or semicircular headdress or part of a headdress, falling over the head and shoulders.

Vein (*Geol.*) A fissure in the Earth's crust which has been filled with some rock or mineral of a different character and origin from the surrounding rock. In many cases veins are formed of igneous rock, *e.g.* Granite. *Cf.* MINERAL VEINS *and* METALLIFEROUS VEINS.

—— (*Zool.*) The term applied to the vessels conveying blood towards the heart. The walls are thin and easily distended, and the blood pressure in the veins is slow and variable. *See* ARTERY *and* HÆMOGLOBIN.

Vein Stuff (*Mining*). GANGUE (*q.v.*)

Velarium (*Archæol.*) A coloured awning supported by masts, to shelter the audience in a Roman theatre, etc.

Velloped (*Her.*) Having the gills of a different tincture from the body, *e.g.* as a cock.

Vellum (*Bind.*) A white and nearly transparent material, consisting of the membranous portion of calf's skin. Similar but superior to parchment, which is made from the skin of the sheep. Much used formerly in antique binding, and still used for expensive bindings, printings, etc. The term is also applied to materials manufactured from other substances.

Veloce; Velocita, Con (*Music*). Rapid.

Velocemente (*Music*). Rapidly.

Velocity of Sound (*Phys.*) Newton calculated theoretically that the velocity of sound in a medium should be equal to the square root of the elasticity, divided by the square root of the density, or

$$v = \sqrt{\frac{E}{\rho}}$$

Taking the isothermal elasticity in the case of a gas, $E = P$, this gives too low a value to be reconciled with the result of experiment. The explanation of this fact is that the adiabatic elasticity, $E = \gamma P$, should be taken; the correct equation is, therefore,

$$v = \sqrt{\frac{\gamma P}{\rho}}$$

Cf. ELASTICITY OF GASES.

Velum. *See* VELARIUM.

Velvet. A plain fabric with a fine pile or fur surface of silk, made from two warps. Three picks of weft having bound both warps by twill or tabby tie, the pole or pile warp is alone raised, and a grooved wire placed under it transversely, groove upwards. The weaving is proceeded with until three wires altogether are in the cloth, when the first wire is cut out by means of a sharp instrument, called a truvat, being drawn along the groove of the wire. This operation produces the pile. *See* WIRE.

Velveteen (*Cotton Manufac.*) A heavy backed fabric woven in the grey state and afterwards dyed. It has a surface composed of small weft floats arranged in regular order. These floats are afterwards cut so as to form a furry and silky pile, like velvet in appearance.

Velvet Finish (*Woollen Manufac.*) Velvet or vertical pile obtained by the process of raising on woollen fabrics, such as rugs. *See* PILE.

Vena Contracta (*Eng.*) A stream of liquid issuing from an opening has in general a diameter smaller than that of the opening. Such a jet or stream is termed a Vena Contracta. The amount of contraction depends upon the average angle at which the particles of the liquid are approaching the opening.

Venation (*Botany*). The system of branching and arrangement of the veins or vascular bundles (*q.v.*) in leaves.

Veneer. A thin layer of some valuable material, wood, ivory, mother-of-pearl, stone, etc., which is fixed to a commoner surface for the sake of effect. Veneers of wood are cut from the log by means of long knives or saws, the log being in some instances rotated in contact with the cutting edge, and are afterwards planed, shaped, and polished by machinery.

Veneer Cutter. *See* VENEER.

Veneering Hammer (*Cabinet Making*). A tool with a wide, thin pane, used for pressing out superfluous glue from beneath the veneer when it is being fixed in position.

Venetian (*Woollen or Worsted Manufac.*) A fine twilled cloth, usually twist warp, and made chiefly for covert coatings.

Venetian Blind. A blind made of laths of wood supported transversely by two or more tape ladders, and so arranged that when the blind is full open the laths lie in a horizontal plane and the series of openings admit light. By adjusting a cord, the laths can be turned at an angle so as to overlap each other and exclude light.

Venetian Glass. This is inferior to English glass in purity and lustre, but is capable of being made into lighter forms, for which it is noted. *See under* GLASS MANUFACTURE.

Venetian Red (*Dec.*) A pale red pigment largely used in house and coach painting, and resembling ochre or ferric oxide in composition according to the method adopted in its manufacture. Formerly the term Venetian Red was applied to a natural oxide of iron selected for its peculiar colour and being less purplish than Indian red. It is now almost wholly manufactured by calcining either green vitriol or ochre.

Venetian Shutter. A frame filled in with louvers (*q.v.*)

Venetian Swell (*Music*). The name given to the *swell* in organs. The shutters of the swell box are generally hung horizontally, and shut by their weight; when hung vertically they have a spring to shut them. Many organs have a balanced swell which enables the organist to leave the shutters at any angle. *See* MUSICAL INSTRUMENTS, *p.* 440.

Venetian Window (*Build.*) The name given to a window frame divided into three lights by mullions.

Venice Turpentine (*Dec.*) An oleoresin obtained from the common Larch, and used in varnish making. It is of a yellowish colour, is thick like honey, and is soluble in both essential and fixed oils, as well as in ether and alcohol. It melts at 808° F., and has a specific gravity of 0·856. *See also* TURPENTINE.

Venice White (*Dec.*) A white pigment made by mixing together equal parts of barium sulphate (barytes) and white lead.

Vent (*Foundry*). A narrow passage made by thrusting a wire into the sand of a mould to allow of the escape of gases while molten metal is being poured in. In certain cases where these openings are insufficient, actual pipes, termed VENT PIPES, are inserted.

—— (*Geol.*) *See* VENT, VOLCANIC.

Ventil (*Music*). (1) A valve letting in or cutting off wind from certain stops in organs. (2) A valve which when opened allows the wind to traverse a greater length of tube of brass instruments. *See* VALVE HORN, *p.* 435; VALVE TRUMPET, *etc.*

Ventilating Fan. A fan used either for forcing fresh air into a space, or for extracting foul air. *See also* SANITATION.

Ventilation. *See* SANITATION (p. 636), ASPIRATION, *and* CUBIC SPACE.

Ventilation of Sewers (*Civil Eng.*) This is best effected by vertical shafts of sufficient height above the ground to carry the noxious gases away from the traffic, and as far as possible away from houses: ordinary manholes and openings at the ground level are objectionable.

Ventilation of Tunnels (*Civil Eng.*) A long tunnel is most easily ventilated by means of shafts. In cases where the tunnel lies at a great depth (*e.g.* where it passes under a hill) shafts become impossible, and large fans may be used, as is the case in the Severn, Mersey, and Simplon Tunnels.

Ventilator. A specially constructed air passage in a building; a shaft in a mine, etc. For examples refer to ARNOTT'S VALVE, SANITATION (p. 636), *and* MINING.

Venting (*Foundry*). The formation of VENTS by thrusting a wire or thin rod, termed a VENT WIRE, into the sand of a mould. *See* VENT.

Vent Pipes (*Foundry*). *See* VENT.

Vent, Volcanic (*Geol.*) The opening or fissure through which volcanic products are ejected. The lava, etc., which filled the vent may remain as a solid core after every other trace of the original volcano has been removed by denudation, and ancient vents accordingly form very characteristic geographical and geological features.

Vent Wire (*Foundry*). *See* VENTING.

Venus (*Astron.*) The planet between the Earth and Mercury. Distance from Sun, 67,200,000 miles. Diameter, 7,700 miles. Periodic time, 0·62 years

Veratrine (*Botany*) An alkaloid used medicinally; obtained from *Veratrum* (a genus of *Liliaceæ*), and from another liliaceous plant, the *Cevadilla* (*Schœnocaulon officinale*).

Verde Antico. A green coating formed on the surface of ancient bronzes by the action of the elements. *See* PATINA.

Verdigris (*Chem.*) Is usually a mixture of basic copper acetates; blue verdigris is chiefly $CuO \cdot Cu(C_2H_3O_2)_2 \cdot 6H_2O$, while light blue and green products contain $Cu(C_2H_3O_2)_2 2CuO \cdot {}_2H_2O$. They are used as paints in the preparation of other copper containing paints, and to a small extent in medicine (externally). Verdigris is made in England by exposing plates of copper to the action of cloths which have been soaked in pyroligneous acid; the plates are then exposed to air, dipped in water, again exposed, and the product scraped off, the process being repeated till the copper is used up. The process requires several weeks.

Verditer (*Paint.*) A pale green pigment consisting of basic carbonate of copper. It is now but little used. Blue verditer is also made, and consists generally of copper carbonate, copper oxide, and copper sulphate. Being somewhat fugitive it is not much used.

Verdure (*Art.*) The term is applied to tapestry in which the design consists wholly or principally of trees or foliage.

Verge (*Archæol., etc.*) A rod, staff, or mace; used as an emblem of authority or as an ensign of office.

—— *or* **Pallet Arbor** (*Clocks*). The arbor, or spindle, to which the pallets are fixed. This arbor also carries the crutch, by means of which the impulse communicated to the pallets is transmitted to the pendulum.

Verge Board (*Build.*) *See* BARGE BOARD.

Vermiculate (*Architect., etc.*) Adorned with tracery having the character of the tracks made by worms.

Vermiform Appendix (*Zool.*) *See* CÆCUM.

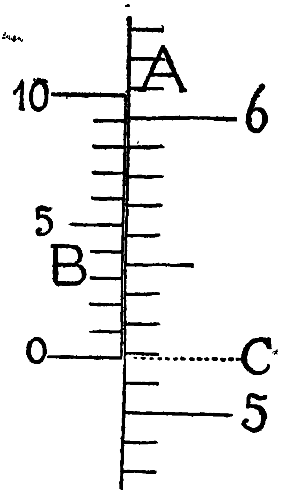
Vermilion (*Paint.*) A bright red heavy pigment made by heating sulphur and mercury. Its chemical name is mercuric sulphide. It was formerly used very largely in painting when a bright scarlet red was required, but it is now being gradually supplanted by the vermilionettes (*q.v.*) Vermilion has a good body, but is not quite permanent to light. A protective coat of varnish is therefore necessary when it is used for outside painting. The manufacture of vermilion in this country is a secret process which is very jealously guarded. Vermilion cannot be mixed with white lead because of the sulphur it contains. *See also* MERCURY COMPOUNDS.

Vermilionette (*Paint.*) A somewhat vague term, which is applied generally to a group of red pigments, mostly made from eosine, which are intended to be used as substitutes for vermilion. Vermilionettes are sold under a variety of names such as signal red, Markeaton red, fast red, post office red, etc. When protected by varnish the best vermilionettes remain almost permanent. Many of them, however, possess the disadvantage that they "bleed," *i.e.* come through any subsequent coat of paint which may be applied over them.

Vernal Equinox (*Astron.*) *See* EQUINOXES.

Vernier. A device to facilitate the accurate reading of a divided scale. It consists of a small movable scale, which is graduated in such a manner that $n + 1$ or $n - 1$ of its divisions are equal in length to n divisions of the original scale. Each division of the vernier is therefore less (in the first case) or more (in the second case) than a scale division, by $\frac{1}{n}$ of the length of a scale division. In the figure, nine divisions

of the scale A are equal to ten divisions of the vernier B. The zero line of the vernier is brought into such a position that it coincides with the point whose position is to be measured on the scale A; in the figure this point, which is marked C, lies between 5·1 and 5·2 on the scale. The graduation line 8 of the vernier coincides with the line 5·9 on the scale: it can be seen by inspection that the zero line of the vernier is ·8 of a scale division above the line 5·1 on the scale: hence the reading required is 5·18. In using this vernier the position of its zero line is first read to the nearest whole division on the scale, and the line on the vernier which coincides with a line on the scale indicates the next decimal place. By this means a scale divided into tenths of the major scale division can be read with accuracy to hundredths. The smallest length which can be read off on the vernier is termed its LEAST COUNT; if n divisions of the vernier are equal in length to $n + 1$ or $n - 1$ divisions of the scale, the least count is $\frac{1}{n}$ of a scale division, since this is the actual difference between one scale division and one vernier division.



Verschiebung, Mit (*Music*). The equivalent in German for *una corda*; *ohne verschiebung* being the equivalent for *tre corde*.

Verse (*Music*). Those portions of a service or anthem which are to be sung by one performer to each part. The other portions, except solos, are called the "full."

Versed Sine. *See* TRIGONOMETRICAL RATIOS.

Versin. VERSED SINE; *see* TRIGONOMETRICAL RATIOS.

Verso (*Print, etc.*) (1) The left-hand page; *cf.* RECTO. (2) The reverse of a coin or medal; *cf.* OBVERSE.

Vert. The heraldic tincture green. Represented by diagonal lines drawn from dexter chief to sinister base of the shield. *See* HERALDRY.

Vertebrata (*Zoology*). A division of the animal kingdom, characterised by having a backbone or vertebral column.

Vertical. Upright, in the direction along which gravity acts, or normal to the surface of a liquid at rest. A vertical line is easily found in practice by means of a fine cord carrying a weight, *i.e.* a plumb bob. The term vertical is often erroneously used instead of perpendicular or normal (*q.v.*)

Vertical Boiler (*Eng.*) *See* BOILERS.

Vertical Circle (*Astron.*) A great circle passing through the zenith and nadir of the celestial sphere. *See* PRIME VERTICAL.

Vertical Engine (*Eng.*) Any engine whose cylinder is vertical. *See* STEAM ENGINE.

Vertical Section. The section (*q.v.*) of an object by a vertical plane.

Vesica Piscis (*Architect.*) The name given to a figure obtained by the intersection of two circles. It is used in window tracery and other features in Gothic architecture.

—— (*Art*). A figure of pointed oval form, used as a symbol of Christ. An aureola used in representations of the Trinity or of the Virgin is generally of this form. *See* AUREOLA *and* GLORY.

Vesicular Structure (*Geol.*) A cellular structure found in lavas, slags, etc., in which a number of spherical cavities have been produced by steam or other gases before the consolidation of the rock.

Vestry. *See* SACRISTY.

Vesuvianite. (*Min.*) *See* IDOCRASE.

Veuglaire (*Arms*). A sixteenth century breech-loading cannon, having a detachable powder chamber.

Vexillum (*Archæol.*) A battle signal or flag, either fixed or carried by a vexillary (standard bearer).

—— (*Her.*) A scarf, encircling a pastoral staff.

Viaduct (*Civil Eng.*) A bridge consisting of a series of arches of masonry or other material, or some other form of structure, intended for carrying a roadway or railway (1) over a valley, etc.; (2) over some existing channel of communication.

Via Lactea (*Astron.*) *See* MILKY WAY.

Viameter (*Surveying*). A wheel with an arrangement for recording the distance passed over when it is rolled along the ground.

Vibrante (*Music*). Tremulous.

Vibration (*Eng.*) In engineering this term is usually applied to an intermittent or irregular motion, which is generally of an undesirable character, and is rarely used to describe any regular motion of the true character of vibrations.

—— (*Phys.*) A periodic movement of small extent which may take a great variety of forms, not confined to one plane.

Vibrator Roller (*Print.*) Used in connection with printing machines. *See* TYPOGRAPHY.

Vibrio (*Biol.*) Bacteria in the form of threads, with bent joints.

Vicar Choral (*Music*). A lay vicar of a cathedral choir.

Vice (*Eng.*) The tool used for holding the smaller pieces of work while being operated upon; it consists of a pair of jaws which can be caused to approach, or recede from, each other by a powerful screw or other device. There are very many forms and sizes.

Vice Bench (*Eng.*) A strong bench to which a vice can be attached.

Vicia (*Botany*). A genus of *Leguminosæ* represented by the vetch, the tare, broad bean, etc.

Victoria Green (*Dec.*) Another name for BRUNSWICK GREEN (*q.v.*) *See also* DYES AND DYEING.

Victoria Red (*Dec.*) A vermilionette (*q.v.*)

Vienna Lake (*Dec.*) Another name for CRIMSON LAKE (*q.v.*)

View (*Art*). A picture or sketch representing a landscape or seascape. *See also* PRIVATE VIEW.

View Finder (*Photo*). An instrument employed with hand cameras to show when the image will fall in the desired position on the sensitive plate.

View Meter (*Photo*). An instrument used for ascertaining the amount of subject included on a given size plate with the lens employed, without the necessity of setting up the camera.

Vignette. (1) In old manuscripts, an initial letter decorated with leaves and tendrils. (2) A head or tail piece in a book. (3) A drawing, photograph, or other illustration having a background that gradually shades off and merges into the ground on which the print is made.

Vignetting (*Photo*). A method of printing in which there is a gradual softening or shading off of the photograph towards the edges. This is effected by some form of mask or screen.

Vignoles Rail (*Civil Eng.*) *See* RAILWAYS, *pp.* 597-8.

Vigogne Yarn (*Woollen Manufac.*) Yarn composed of a mixture of cotton and wool.

Vigore, Con (*Music*). With vigour.

Vigorosamente (*Music*). Vigorously.

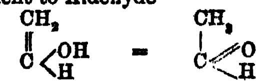
Villi (*Zool.*). Minute finger-like projections from the wall of the ileum. They project into the cavity of the intestine, and absorb the nutriment from the chyme.

Vinasse (*Chem.*) *See* TRIMETHYLAMINE.

Vine (*Botany*). The numerous products of the grape vine, *Vitis vinifera* (order, *Vitaceæ*), are well known. The dried fruits form raisins, and the small seedless berries of the black Corinth grape constitute currants.

Vinegar (*Chem.*) An impure dilute acetic acid. The amount of acetic acid varies from 4 to 15 per cent. Besides water and acetic acid other substances are present, and the nature of these depends on the method of manufacture and adulteration. Wine vinegar is made by allowing inferior wine to ferment in casks with good air access and at a proper temperature. This vinegar is pale yellow to red in colour, and contains a little alcohol, ethyl acetate, and other esters to which its aroma is due, and dissolved solids such as alkaline acetates, tartrates, and phosphates. Malt vinegar is made by allowing a wort such as is prepared in the manufacture of alcohol (*q.v.*), with some added alcohol, to drip over deal shavings covered with a growth of the mycoderma aceti (the organism which oxidises alcohol to acetic acid) and contained in a large oak tub; the supply of dilute alcohol must be regulated, a suitable supply of air provided for, and a proper temperature maintained. In starting such a process the shavings must have been coated with the organism first by allowing vinegar to stand in the tubs some days. A stronger vinegar is made by running the product with added alcohol through a second tub; but an acid over 15 per cent. cannot be prepared in this way, for the organism ceases to be effective in an excess of acetic acid. Such vinegar is usually coloured by caramel. Occasionally it is adulterated with a mineral acid, but this is illegal; it may contain traces of arsenic if the malt used in its preparation contained arsenic (from the fuel of the malt-kiln). An inferior vinegar is made from pyroligneous acid (*q.v.*). Vinegar is used to some extent in medicine, *e.g.* for sprains, and in fevers (lowers the temperature and checks perspiration).

Vinyl (*Chem.*) A name given to the group $CH_2{=}CH$; thus vinyl bromide is $CH_2{=}CHBr$, and vinylamine is $CH_2{=}CHNH_2$. Vinyl alcohol is not known, as it undergoes rearrangement to Aldehyde



Viol da Braccia; Viol d'Amore; Viol da Gamba (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 427.

Viola (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 427.

Violet (*Colours*). Most of the violet colours now used are made from the anilines which are precipitated on a white base. None of them are quite permanent.

Violin (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 427.

Violin Diapason (*Music*). A metal organ stop of small scale and stringy tone.

Violino Principale (*Music*). The leader of the orchestra.

Violino Ripieno (*Music*). Violin parts required for filling in or strengthening the *tutti*.

Violle (*Light*). A unit of intensity of light. It is equal to the intensity of illumination emitted (in a perpendicular direction) by one square centimetre of platinum at the temperature at which it melts.

Violoncello (*Music*). A metal organ stop in the pedal organ of 8 ft. tone. It is the octave of the violone. *See also* MUSICAL INSTRUMENTS, *p.* 427.

Violone (*Music*). A metal organ stop in the pedal organ of 16 ft. tone. It is an open Diapason or Gamba of small scale.

Virginal (*Music*). The name applied in England during the sixteenth and seventeenth centuries to all kinds of musical keyed-instruments played by quills or jacks, but more especially to those of the Elizabethan period; *e.g.* the spinet, harpsichord, etc.

Virtu, Vertu (*Art*). This terms refers generally to decorative objects that are either old, rare, or curious; *objects of virtu.*

Virtual Current (*Elect.*) The effective value of an alternating current depends not upon its average value, but is equal to the square root of the average value of the square of the current. Thus if C_0 be the maximum value of a current following a sine law, C the value at any instant t, $C = C_0 \sin \theta$, and the virtual value, $\overline{C}$, is given by the equation

$$\overline{C} = \frac{C_0}{\sqrt{2}}.$$

Virtual Image (*Phys.*) If rays diverging from a point A behave after reflection or refraction as if they diverged from a second point B, then B is a Virtual Image of A.

Virtual Voltage (*Elect. Eng.*) The square root of the mean value of the square of the voltage of an alternating current. If the E.M.F. vary according to

a sine law, and V_0 be the maximum voltage, V the virtual voltage, then

$$V = \frac{V_0}{\sqrt{2}}.$$

Cf. VIRTUAL CURRENT.

Virtuoso; *pl.* Virtuosi (*Art*). One who has a critical knowledge of the fine arts, or of some branch of the fine arts; an art critic. *Cf.* CONNOISSEUR.

Viscose. A soluble form of cellulose obtained by treating the cellulose with alkali and bisulphide of carbon. *See* CELLULOSE *and* WOOD PULP.

Viscosimeter *or* **Viscometer.** *See* VISCOSITY.

Viscosity. The property possessed by a liquid of resisting deformation. The fact that liquids do resist attempts to alter their shape becomes noticeable when a liquid is transferred from one vessel to another through a tube; it must then temporarily assume the form of the interior of that tube. In many cases the resistance of a liquid (take castor oil as an excellent example) to deformation can be observed by simply tilting a wide bottle containing some of it. The liquid assumes the new form thereby given to it sluggishly and reluctantly. This resistance is called viscosity. Being often associated with weight and stickiness, it is confounded with these properties, especially with the latter, although it has nothing to do with either of them. The words "viscous" and "viscosity" nevertheless are derived from *viscum*, the Latin word for birdlime. The opposite of viscosity is mobility. We speak of water or alcohol as mobile liquids, of castor oil or fused butter as viscous liquids; but the difference is one of degree only, and there are liquids so viscous and solids so plastic that we see what thin partitions divide the solid from the liquid, and that the distinction between the two is arbitrary, and one of convenience merely. A mobile liquid may be defined as one which resists change of form so little that the human eye cannot notice the resistance. The practical significance of viscosity is very great in respect of lubricants, all of which possess a perceptible degree of viscosity. The usual standard of measurement is rape oil. The viscosity is measured by the time which the known volume of the liquid takes at a given temperature to flow through an aperture of known form and dimensions under a known mean pressure. The instrument used for comparing viscosities is called a VISCOSIMETER (or, by a shortened form, VISCOMETER). Redwood's viscometer, which is a good type, consists of a silvered copper cylinder about 2 in. in diameter and about 4 in. deep, to receive the liquid to be tested. The liquid flows out at the bottom through an agate jet, which is opened by raising a valve by means of a vertical spindle. The support of this spindle also carries a thermometer to ascertain the temperature of the liquid under examination. The cylinder is immersed in a jacket, whereby it is maintained at a constant temperature. Inside the cylinder there is a mark, so that the liquid can always be filled to exactly the same depth. The whole instrument is mounted on a tripod with levelling screws, so that the axis of the cylinder may be made truly vertical. This is essential to the proper outflow from the jet. A 50 c.cm. flask is put below the jet, and the exact time required to fill it to the mark is accurately noted. The following are a few illustrative examples of the time taken:

	Seconds.
Water	28
Cocoanut oil	64
Linseed oil	212
Walnut oil	232
Safflower	249 to 294
Poppy seed oil	254 „ 259
Earth nut oil	307 „ 429
Garden cress oil	322
Radish seed oil	385

A. S. J.

Viscountess (*Build.*) A roofing slate measuring 18 by 10 in. *See* SLATES.

Visible Horizon. The irregular line where the sky appears to meet the most distant visible objects on the earth's surface. *See also* OFFING.

Visor (*Arm.*) The front part of a helmet containing the openings for seeing and breathing. The visor was sometimes movable and sometimes otherwise.

Vitreous Copper Ore (*Min.*) *See* COPPER GLANCE.

Vitreous Electricity. Electricity of the same sign as that obtained by rubbing glass with silk; positive electricity.

Vitreous Rocks (*Geol.*) Eruptive rocks having a glassy structure and appearance, *e.g.* OBSIDIAN (*q.v.*)

Vitriol, Blue (*Min.*) *See* CHALCANTHITE.

Vitriol Chamber (*Chem. Eng.*) The "chamber" used in Sulphuric Acid Manufacture (*q.v.*)

Vitriol, Green (*Min.*) *See* COPPERAS.

Vitriols (*Chem.*) Crystallised sulphates of copper, iron, zinc. See under compounds of these metals. Oil of vitriol is sulphuric acid (*q.v.*)

Vittæ (*Botany*). The oil ducts found on the fruits of Umbelliferous plants.

Vivace, Vivo (*Music*). Lively.

Vivianite (*Min.*) A hydrous ferrous phosphate, $Fe_3P_2O_8 + 8H_2O$. Contains ferrous oxide 41·2, phosphoric acid 31·2, water 27·5 per cent. Monosymmetric, in sheaves of diverging crystals, green to indigo blue. In association with other iron ores in the mines of Devon and Cornwall, and in many foreign localities. Also in peat bogs, old drain pipes, and some clays.

Vizor. *See* VISOR.

V Joint (*Carp. and Join.*) A joint between two boards, of which the edges to be joined together are chamfered.

Vocalisation (*Music*). *See* SOLFEGGIO.

Vocal Score (*Music*). *See* SCORE, *p.* 647.

Voce di Petto (*Music*). The chest voice.

Voce di Testa (*Music*). The head voice.

Voice (*Music*). Voices are of seven kinds, *viz.* bass (the lowest), baritone, tenor, alto or counter-tenor—these four are men's voices—contralto, mezzo-soprano, and soprano (the highest)—these three are women's voices. Boys' voices are generally called treble. *See also* STAVE, *p.* 710.

Voicing (*Music*). The art of obtaining a particular quality of tone in an organ pipe and of procuring uniform strength and quality throughout the entire

stop. Voicing is one of the most delicate and artistic parts of the organ builder's art, and it is seldom, if ever, that a "voicer" is good at both "flue" and "reed" voicing.

Void (*Build.*) An opening or empty space, *e.g.* the opening spanned by a beam, arch, rafter, etc.

Voix Celeste (*Music*). A stop on organs and harmoniums producing a tone of a waving character. *See pp.* 441 *and* 443.

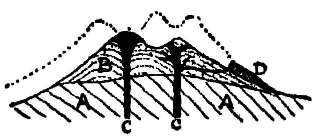
Volante (*Music*). Flying.

Volatile Alkali (*Chem.*) An old name for AMMONIA (*q.v.*)

Volcanic Ash (*Geol.*) Dust, scoriæ, and cinder-like fragments ejected from a volcano; this material may become consolidated in various ways into a more or less coherent rock, generally termed a TUFF.

Volcanic Rocks (*Geol.*) A general term for LAVA, TUFF, etc. (*q.v.*)

Volcano (*Geol.*) A volcano is essentially an opening in the crust of the earth, from which are ejected lava, fragments of rock, dust, steam, and sometimes other gases. The accumulation of the solid materials round the mouth of the opening, or CRATER, gives rise in most cases to a more or less permanent cone, which is often spoken of as the volcano itself. The lower part of the opening, or vent, extends downward for an unknown distance, and finally communicates with a region of molten or intensely heated materials. No smoke, in the proper sense, is poured out from a volcano, the dense clouds of steam, heavily charged with dust, simulating the appearance of smoke; and the reflection of the glowing lava of the crater often adds the appearance of flame and fire, though neither of the latter occurs. It follows therefore that the old definition a "burning mountain" is incorrect. The majority of active volcanoes are found in lines following the sea coast, *e.g.* on the western shores of the American continent, or the north-eastern shores of the Indian Ocean. The illustration shows a more or less diagrammatic section through the extinct volcanic remains of Largo Law in Scotland.



VOLCANO.

A. Original Rocks (Carboniferous).
B. Tuffs.
C. Basalt filling the vents.
D. Lava Sheet.

Volonte, à (*Music*). At will or pleasure; the equivalent of *ad libitum*.

Volt (*Elect.*) The unit of electromotive force employed in practice. It is that electromotive force which when applied to a conductor whose resistance is 1 Ohm (*q.v.*) produces in it a current of 1 Ampère (*q.v.*) The E.M.F.'s of most of the ordinary primary cells lie between 1 and 2 volts.

Volta (*Music*). Time. *Prima volta*, first time (*see* PRIMA); *seconda volta*, second time (*see* SECONDO).

Voltage (*Elect. Eng.*) Potential difference, usually expressed in Volts.

Voltaic (*Elect.*) An old term applied to electric phenomena produced by the current obtained from batteries.

Voltaic Cell (*Elect.*) *See* CELLS, PRIMARY.

Voltameter (*Elect.*) A piece of apparatus in which chemical decomposition is effected by the passage of an electric current; if the amount of such decomposition be measured, *e.g.* the volume of a gas given off, or the weight of a metal deposited on the Kathode, the quantity of electricity which has passed through the cell can readily be calculated.

Volti (*Music*). Turn; as *volti subito*, turn quickly.

Voltmeter (*Elect.*) An instrument for the direct measurement of voltage or potential difference. The main types of voltmeter are as follows:

(1) *Magnetic Voltmeters.*—These are in principle high resistance galvanometers, constructed either with a fixed coil and moving magnet, or preferably with a fixed magnet and moving coil. The moving part is provided with a pointer moving over a scale graduated in volts, by which the potential difference between the two points to which the terminals of the instrument are connected, may be read off. As the direction of the deflection depends upon the direction of the current, these types are only suitable for continuous currents.

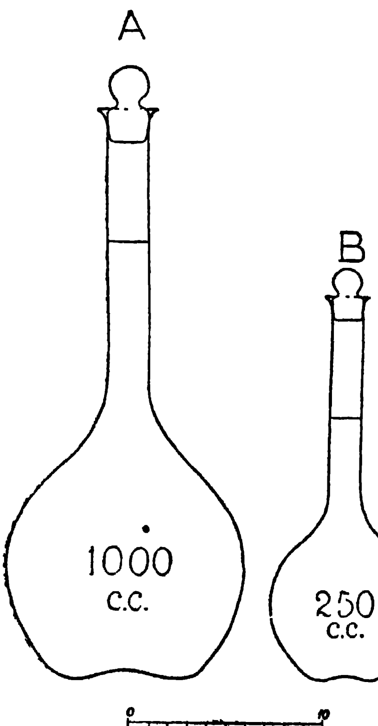
(2) *Hot Wire Voltmeters.*—In these the expansion of a thin wire of high resistance, when heated by the passage of a current, is caused to move a pointer. Cardew's Voltmeter is one of the best known forms. Such instruments are equally suitable for alternating or for continuous currents.

(3) *Electrostatic Voltmeters.*—These depend on the principle of the Electrometer (*q.v.*), which itself forms a voltmeter applicable to many purposes. In commercial instruments, the moving needle is attached to a light pointer, as in the cases above mentioned. Where great sensitiveness is required, a number of needles or vanes are mounted upon one shaft, and a corresponding number of fixed vanes or quadrants are arranged so as to produce simultaneously an attraction on the moving vanes. Voltmeters of this type possess many advantages over the two former kinds and are much used in alternate current work.

Volumetric Analysis (*Chem.*) Suppose we have two substances A and B which react in solution in exact accordance with a known equation. Then, if the end of the reaction can be easily determined by inspection or by the addition of a small amount of an indicator (*q.v.*), knowing the strength of the solution of A, the strength of the solution of B can be determined by finding what volume of the solution of A, must be added to a known volume of the solution of B in order to obtain a solution which contains excess of neither A nor B. An operation of this kind is a volumetric analysis. It will be seen that a reaction to be employed in volumetric analysis must be rapid and complete, that a balance and measuring instruments are required, that in those cases where the end of the reaction cannot be told by inspection an indicator is required, and that one of the solutions employed in any particular operation must be of known strength. Some of the typical reactions employed will be given further on. The measuring vessels commonly in use are:

(1) FLASKS.—These are pear-shaped or round, and have rather long necks; they should have well-fitting glass stoppers. On the neck there is a circular file mark, so that when the flask is filled up to the mark it will contain the volume marked on the vessel at the temperature marked on the vessel. Sometimes there are two marks on the neck of a flask; in this case the lower mark means that when the flask is filled up to this it contains the volume marked on

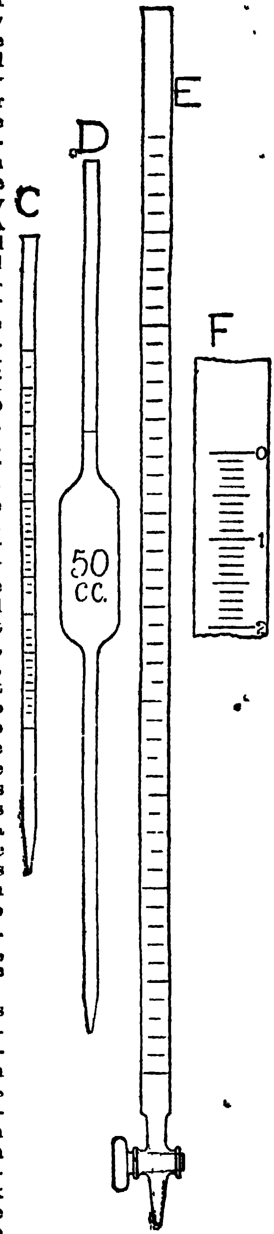
the flask, while the upper mark means that when the flask is filled up to this it will deliver, when it is emptied, the volume marked on the flask—the volume of liquid between the two marks is the amount of liquid that remains adhering to the walls of the vessel when it is emptied. The necks of the smaller flasks are narrow, so that the surface of the liquid in the neck is markedly curved, therefore in filling the flask up to the mark it is done so that the tangent plane to the lowest point of the curve lies in the plane of the circular file mark on the neck. Obviously the final adjustment of the liquid to the mark must be made with the file mark held on a level with the eye of the experimenter. These remarks as to the curved surface and reading apply equally to burettes and pipettes; also the neck of a flask, a burette, and a pipette can only be read accurately when vertical. Convenient sizes for flasks are 2 litres, 1 litre, 500 cc., 250 cc., 200 cc., 100 cc. Flasks A and B of 1,000 cc. and 250 cc. content are shown in the diagram drawn to scale.



FLASKS.

(2) BURETTES.—A burette is a straight tube open at one end and narrowed at the other end to an almost capillary tube; near the narrowed end there is a glass tap, or other device for regulating the flow of liquid from the burette. Starting a few centimetres from the wide end are file marks at every tenth of a centimetre down to 50 cc.; in the best burettes the uppermost file mark goes completely round the burette, at 0·5 cc. the mark goes about a third of the way round, at 1 cc. completely round, and so on all the way down. Smaller burettes are used sometimes. E is a 50 cc. burette; each division represents 1 cc., the subdivisions being shown on a larger scale at F.

(3) PIPETTES.—These are of two kinds—bulb and straight. The first form consists of a cylindrical bulb, on to each end of which rather narrow tubes are sealed; the delivery end is narrowed to an almost capillary opening, while the other end is of uniform bore and marked at a convenient distance from the bulb with a file mark going completely round the tube. A pipette can be marked with a containing and a delivering mark—usually only the latter mark is required. The straight form is employed for delivering smaller quantities of liquid than the bulb form; it is merely a burette without a tap. Pipettes are used either to withdraw (containing mark) a definite volume of liquid from a known volume of it or to transfer (delivery mark) a definite volume of liquid from one vessel to another. Convenient sizes are 100 cc., 50 cc., 25 cc., 20 cc., 10 cc., 5 cc., 2 cc. The first five are usually bulb shape, the other two bulb or straight; in the latter case they are graduated in fractions of a centimetre just as a burette is, only a 2 cc. pipette may be graduated in twentieths of a centimetre or even less. D is a 50 cc. bulb pipette and C a 5 cc. straight pipette. E, D, and C are drawn to the same scale as A and B.



BURETTE AND PIPETTES.

One of the solutions employed in any process of volumetric analysis must be of known strength, and this is called the standard solution. But the strength of the standard solution is not chosen at random; in scientific work it is customary to make solutions having some simple relation to the gram molecular weight dissolved in 1 litre; but an analyst will often make a solution of such a strength as to bear a simple relation to the particular substance he desires to estimate. We shall only deal with the

former kind of solution. These are so made that equal volumes contain chemically equivalent amounts of the dissolved substances. A solution which contains 1 gram of replaceable hydrogen, or the chemical equivalent of this of the active element or group, dissolved in 1 litre of the solution is called a NORMAL SOLUTION; then any other solution can be expressed in terms of a normal solution by dividing the number of grams of the substance contained in 1 litre by the number of grams of the substance contained in 1 litre of a normal solution.

Examples.—Hydrochloric acid, HCl, has the molecular weight 36·5, so that 36·5 grams of hydrochloric acid contain 1 gram of replaceable hydrogen; therefore 36·5 grams of hydrochloric acid in a litre is a normal solution of this acid; 3·65 grams in a litre would be a deci-normal solution, and so on. Sulphuric acid, H_2SO_4, has the molecular weight 98, so that 98 grams of this acid contain 2 grams of replaceable hydrogen, therefore a normal solution will contain 49 grams of the acid in a litre.

Caustic soda, NaOH, has the molecular weight 40; in it the monovalent atom of sodium may be regarded as having replaced 1 hydrogen atom in 1 molecule of water, so that a normal solution will contain 40 grams of caustic soda in a litre. Sodium carbonate, Na_2CO_3, has the molecular weight 106; in it the sodium atoms may be regarded as having replaced 2 hydrogen atoms in carbonic acid, H_2CO_3, so that a normal solution will contain 53 grams of sodium carbonate in a litre. Potassium permanganate, $KMnO_4$, has the molecular weight 158, and behaves as an oxidising agent in presence of excess of sulphuric acid and an oxidisable substance in accordance with the equation

$$2KMnO_4 + 4H_2SO_4 = 2KHSO_4 + 2MnSO_4 + 3H_2O + 5O.$$

That is, $2KMnO_4$ gives 5 atoms of oxygen which are equivalent to 10 atoms of hydrogen, and hence a normal solution of potassium permanganate contains $\frac{2 \times 158}{10} = 31{\cdot}6$ grams per litre. The operation of finding what volume of a standard solution must be added to a known volume of a solution of unknown strength to bring about a definite change so that no excess of either of the dissolved substances remains, is called a titration. Some of the principal operations in volumetric analysis are the following:

1. A standard alkali is used to determine the strength of an acid. The standard alkali can be made by weighing out 53 grams of pure sodium carbonate, dissolving this in distilled water and making up to 1 litre by the addition of distilled water; or a clean piece of sodium could be weighed, thrown into water, and the solution of caustic soda so obtained made up to a suitable volume with distilled water.

2. The converse of 1—that is, a standard acid—is used to determine the strength of an alkali. The standard acid could be made by taking the specific gravity of a fairly concentrated acid, then by means of a table finding what volume of distilled water must be added to make a litre of a normal solution of the acid. For instance, if the density $\left(\frac{20^\circ}{4^\circ}\right)$ of some sulphuric acid is 1·2, it is only necessary to take 296·9 cc. of this acid and make it up to 2 litres to have a normal solution of sulphuric acid. Let some normal sulphuric acid be placed in a burette, and 25 cc. of a solution of sodium carbonate be placed in a flask; add 1 drop of methyl orange solution and run in the sulphuric acid till the liquid just shows pink; let 30 cc. of the acid be required. Thus 1 cc. of the carbonate requires $\frac{30}{25}$ cc. of normal sulphuric acid to neutralise it, and therefore the carbonate must be $\frac{30}{25}$ times normal $= \frac{30}{25} \times 53$ grams Na_2CO_3 per litre.

3. A standard solution of potassium permanganate is used to oxidise a solution of a ferrous salt of a solution of oxalic acid or of an oxalate. To make the standard permanganate 3·16 grams of the chemically pure substance are dissolved in water and made up to a litre to obtain a deci-normal solution. Such a solution may have to be "standardised"—that is, may have to have its strength verified. In this case chemically pure ferrous ammonium sulphate may be used to verify the permanganate; a known weight of this salt is taken dissolved in water and titrated in presence of excess of sulphuric acid against the permanganate. Suppose the weight of the iron salt to be so chosen that it should take precisely 50 cc. of $\frac{n}{10}$ permanganate to oxidise it, and we find that it requires 50·25 cc. of the permanganate prepared as above; then this permanganate is $\frac{50}{50{\cdot}25}$ times deci-normal $= {\cdot}995 \times \frac{n}{10}$. Let ·56 grams of a specimen of iron be dissolved in dilute sulphuric acid, the latter being in considerable excess. Run in some of the above permanganate till the pink colour of the permanganate just persists: let 99 cc. be required. Now we have

$2KMnO_4$ gives 5O in presence of sulphuric acid,

$$\text{and } 2FeSO_4 + H_2SO_4 + O = Fe_2(SO_4)_3 + H_2O,$$

that is $\underbrace{2KMnO_4}_{316}$ oxidise $10FeSO_4$, or are equivalent to 10Fe—that is, 1000 cc. $\frac{n}{10}$ permanganate are equivalent to 5·6 grams iron, or 100 cc. $\frac{n}{10}$ permanganate are equivalent to ·56 grams iron; therefore the specimen of iron contains 99 × ·995 per cent. Fe.

4. Solutions of sodium thiosulphate and of iodine (in water containing sufficient potassium iodide to keep it dissolved) are often employed in volumetric analysis. These react in accordance with the equation

$$2Na_2S_2O_3 5H_2O + I_2 = Na_2S_4O_6 + 2NaI + 10H_2O.$$

That is, 2 × 248 grams of crystallised sodium thiosulphate react with 2 × 127 grams of iodine or 248 grams of the former with 127 grams of the latter; and as iodine unites with hydrogen atom for atom, we have: A normal solution of iodine contains 127 grams per litre; a normal solution of sodium thiosulphate contains 248 grams of the crystallised salt per litre. To illustrate the use of the above reaction weigh out 0·435 grams of manganese dioxide into a small flask; add excess of pure strong hydrochloric acid, and pass the chlorine evolved into a considerable excess of potassium iodide solution, so that no chlorine escapes from the solution; then titrate the liberated iodine by a deci-normal solution of sodium

thiosulphate. Suppose 95 cc. of the thiosulphate are required. The following reactions occur:

$$MnO_2 + 4HCl = MnCl_2 + 2H_2O + Cl_2$$
$$Cl_2 + 2KI = 2KCl + I_2$$
$$2Na_2S_2O_3{,}5H_2O + I_2 = Na_2S_4O_6 + 2NaI + 10H_2O.$$

so that $\underbrace{MnO_2}_{87}$ is equivalent to $\underbrace{2Na_2S_2O_3{,}5H_2O}_{2 \times 248}$

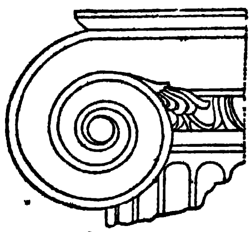
or 43·5 grams manganese dioxide require 248 grams crystallised sodium thiosulphate. Thus 0·435 grams of pure manganese dioxide would require 100 cc. of deci-normal thiosulphate; thus the sample contains 95 per cent. MnO_2.

5. A standard solution of silver nitrate can be used to find the strength of a solution of a chloride. In this case the silver nitrate is put in the burette and the chloride in a white basin; to the chloride a few drops of a solution of potassium chromate are added, and then the silver nitrate is run in. All the chloride is precipitated before the chromate, so that at the moment the precipitate is tinted by the brick-red colour of silver chromate the reaction is at an end, and a simple calculation gives the strength of the chloride. This operation is only possible with neutral solutions.

On the above and a few other reactions are founded a great variety of estimations by volumetric analysis. These processes of volumetric analysis are very accurate and far more rapid than those of gravimetric analysis, and are therefore extensively employed.

W. H. H.

Volute (*Architect.*) The spiral form used in the capitals of the Ionic, Corinthian, and Composite orders. A roughly formed volute is often found in Romanesque capitals.



VOLUTE.

Vorschlag (*Music*). A musical ornament, written as a small note or notes before the note which it embellishes. The time of the vorschlag is taken out of the embellished note. The long, short, and double vorschlag correspond respectively to appoggiatura, acciaccatura, and schleifer, which are all given under ORNAMENTS, *p.* 479.

Vortex Ring. A phenomenon of fluid motion, of which an example is found in the "smoke ring" which is produced by puffing smoke through a tube, or from the lips, or occasionally by steam from the spout of a kettle, or chimney of a locomotive. The fluid forming the ring is in a state of rotation about the centre of the cross-section of the ring itself. The mathematical theory of the properties of vortex rings is of great interest, but too complex for a short description.

Voussoir. One of the series of stones or bricks, fashioned like a truncated wedge, with which an arch is built. *See* ARCH.

Vox Angelica (*Music*). An organ stop consisting of two ranks of pipes of the dulciana type. One of them is tuned sharper or flatter than the other, thus producing a waving effect.

Vox Humana (*Music*). A reed organ stop of very small length and of peculiar construction, supposed to imitate the human voice.

V Thread *or* **Vee Thread** (*Eng.*) The ordinary screw thread of triangular section. *See* SCREWS.

Vulcan (*Astron.*) A supposed intra-Mercurial planet.

Vulcanite *and* **Vulcanising.** *See* RUBBER.

Vulned (*Her.*) Wounded. The pelican is sometimes represented as "vulning herself," in accordance with the idea that this bird feeds her young by pecking at her breast with her beak when she cannot otherwise provide for them. The pelican thus blazoned is also one of the emblems of the Catholic Church.

Vulpinite (*Min.*) A variety of ANHYDRITE (*q.v.*)

W (*Chem.*) The symbol for TUNGSTEN *or* WOLFRAM (*q v.*)

W, w (*Eng., Phys., etc.*) A symbol for Work.

Wad (*Min.*) A synonym for GRAPHITE (*q.v.*) used in the northern counties.

Wadding (*Textile Manufac.*) (1) A thick yarn used in compound cloths to give weight. It lies between the face and the backing threads. (2) Carded cotton in the form of sheets, used for filling out garments, and for other purposes.

Waggon Vault (*Architect.*) *See* BARREL VAULT, VAULT, *and* GROINED VAULT.

Wainscot (*Build.*) A lining for the inner walls of a building, generally extending a part of the way only from the floor to the ceiling. It is usually made of wood, panelled; but other materials, *e.g.* marble, are sometimes employed.

Wainscot Oak. Oak cut radially from the log in order to show the silver grain (*q.v.*)

Wald Flute (*Music*). A wooden organ stop of either 8 ft. or 4 ft. pitch. *See* p. 441.

Waling (*Build., etc.*) The horizontal timbers supporting the poling boards along the sides of a trench.

Wall (*Mining*). The side or boundary of a vein or lode.

Wall Bearing, Bracket, etc. (*Eng.*) A bearing, bracket, etc., so constructed that it can be fixed to, or built into, a wall.

Wall Plate (*Build.*) A horizontal bond timber supported by, or built into, a wall, and itself supporting the ends of joists and rafters. *See* FLOORS, *p.* 128, *and* ROOFS, *p.* 621.

Wall Rib (*Architect.*) A half or three-quarter rib used against a wall in Gothic vaulting. *See* RIB AND PANEL VAULT.

Walnut (*Botany*). The drupaceous (or stone) fruit of *Juglans regia* (*Juglandaceæ*). The stone or shell consists of two valves with leathery ingrowths between the cotyledons of the seed. A green pulp and rind surrounds the shell. *See also* WOODS.

—— (*Dec.*) *See under* GRAINING.

Warble (*Leather Manufac.*) A hole made in a hide or skin by the ox- or bot-fly.

Warehouse. A building for the storage of, or wholesale dealing in, goods.

Warehouse (*Print.*) The department of a printing office which controls the "white" or unprinted paper and the drying, pressing, quiring, etc., of the printed sheets.

Warm (*Paint.*) The term is applied to colours with a red or yellow tone; also to a picture in which these tones predominate, *e.g.* painted in *warm colours.*

Warming. *See* SANITATION, *p.* 636

Warp (*Carp., etc.*) To twist; applied to the twisting and distortion of timber, produced by shrinkage in drying, etc.

—— (*Eng., etc.*) To draw a heavy object along by means of a rope or cable which is coiled on a drum or windlass.

—— (*Lace Manufac.*) A beam or cylinder containing one system of the threads used in the manufacture of lace. *See* LACE MANUFACTURE.

—— (*Textile Manufac.*) The term applied to the series of spun threads, usually stronger and harder twisted than the weft, that run lengthwise of a piece of cloth in the loom. In the silk trade, the term "CANE" is synonymous with warp. *See also* WEAVER'S WARP.

——, **Backing** (*Textile Manufac.*) The method of putting a back to the cloth by using a separate warp.

——, **Centre** (*Textile Manufac.*) This may be either a stitching or a wadding warp. *See* WADDING.

——, **Stitching** (*Textile Manufac.*) A special warp for binding two fabrics together.

Warper's Brasses (*Lace Manufac.*) Rectangular plates of brass, generally ¼ in. by 2 in., with drilled holes, in number according to the purpose they have to serve. A series of them placed end to end form a sley for the production of the warp.

Warping (*Cotton Weaving*). Running together in some definite order a number of threads, from bobbins placed in a creel, so as to form a warp (*q.v.*) which may be prepared for the loom in a convenient form. The ends and length are determined beforehand. There are four distinct methods in Cotton Weaving: (1) Mill. (2) Sectional. (3) Beam. (4) Chain or lease.

—— (*Linen Manufac.*) Arranging the threads of yarn in lengths of one or more webs of cloth, so that they can be put on a beam for the loom. This is done either by winding from a few spools, round a cylindrical creel, till enough threads are put on; or a number of spools can be put on a flat frame and the threads run from these through a reed on to two or more beams. The former is called CHAIN WARPING, the latter BEAM WARPING.

—— (*Textile Manufac.*) An operation performed either by hand or machine. It consists of preparing the warp threads in the requisite order and length for the loom. *See* BEAM, CHAIN WARP, *and* LOOM.

Warping Mill (*Lace Manufac.*) An extended form of reel, such as that used for forming hanks or skeins of cotton, but much more strongly built. It may be 44 quarters, say 400 in. wide, and 3 or 4 yards in circumference. All the threads of the warp are arranged and wound upon this in correct order and length previous to being transferred to the warp beam.

Warp Machine (*Lace Manufac.*) A development of the hosiery or stocking machine. It makes fabric of the most diverse character, from heavy woollen cloth or blanket to the finest silk point net, according to the gauge of the machine. It may be adapted to make imitation crochet lace or lace curtains, its distinctive feature being the production of a looped or crochet stitch in contradistinction to twist-lace.

Warren Girder (*Civil Eng.*) A built-up or lattice girder, consisting of two horizontal members connected by bracing which forms a series of isosceles triangles. The sides of these triangles are alternately struts and ties, *i.e.* one is in compression, the next in tension, and so on.

Wash Dirt (*Mining*). Earthy matter, drift, etc., in which gold is found in alluvial deposits.

Washdown Closet *or* **"Short Hopper"** (*Sanitation*). Consists of a basin with an almost vertical back, so that the excrement falls directly into the water of the trap and not upon the sides of the basin. It should be supplied with a flushing rim, and the junction of the basin and trap, if not in one piece, should be so effected that the internal surface is perfectly smooth, thus obviating any collection of filth. It should be flushed with at least two gallons of water delivered by a 1¼-in. pipe from a water waste preventer fixed at a height of from 5 to 6 ft. to secure sufficient force thoroughly to wash out the basin.

Washer (*Eng., etc.*) A plate (usually in the form of a disc with a hole through the centre) which is slipped over the end of a bolt, and serves as a bed for the nut which is screwed down upon it. Washers are usually of iron, but leather, rubber, etc., are also used for special purposes, *e.g.* in cocks and valves to make watertight joints.

Washing (*Mining*). Separating superfluous matter (dirt, gangue, etc.) from ore by the action of water. The process usually depends upon the different densities of the materials acted upon, the heavy constituents remaining behind while the lighter ones are washed away.

Wash Leather. *See* CHAMOIS LEATHER.

Washout Closet (*Sanitation*). Consists of a basin so shaped that a certain amount of water is detained in it by means of a ridge over which the contents are carried into a siphon trap below. This form of closet requires a strong flush of water in order to carry away the excreta. Not now much in use, as it is not in accordance with the majority of by-laws.

Waste (*Print.*) The surplus sheets of a printed work or job.

—— (*Textile Manufac.*) This may be weavers', warpers', woollen, worsted, or mixed fibre. It is waste yarn that, after opening, is re-carded, and used as a substitute for wool.

Waste Pipe (*Build.*) The pipe that carries away the waste water from a bath, sink, etc.

Waste Preventer (*Plumb., etc.*) *See* WATER WASTE PREVENTER.

Waste Products and their Use. A complete list of waste products in industrial and commercial enterprises, as well as those of domestic origin, would occupy a great deal of space and cover a very large number of important and interesting manufacturing industries. The waste products of domestic origin are mainly of two kinds: (1) Animal refuse derived from the slaughter of animals used for food; (2) Town refuse collected from house to house.

Animal Refuse. Very little of the animal which is killed for human food is wasted. The HIDES are

sent to the tanner, who removes the hair and converts the skin into leather (*see* LEATHER MANUFACTURE), the hair being utilised afterwards as a binding material in the manufacture of plaster for the walls of houses. The larger BONES are used for the production of buttons, knife and tool handles, while the smaller bones are purchased by manure manufacturers, who grind and treat them with acid, to produce fertilising compounds, and a valuable oil is also obtained from these bones (*see* BONE OIL). The BLOOD, of which large quantities are produced in the slaughterhouse, is utilised for the preparation of albumen, or it can be treated for the manufacture of what is known as animal charcoal. From the HORNS of the animal are made combs, cigarette holders, buttons, and similar objects; even waste horn clippings can be utilised for this purpose. The feet of the animals are employed for the production of lubricating oils, such as neat's foot oil. The coarse FAT produces tallow and tallow oil. The INTESTINES are cleansed and converted into catgut, the finer qualities of which are used for violin strings. Another well-known preparation from this source is gold beater's skin. The BLADDERS are utilised for storing lard. The HAIR from various animals finds many uses, for example, the hair from rabbit skins is made into felt hats; the clippings from the hair dressers into wigs, curls, etc.; the skins, according to the animal from which they are obtained, find many uses, the rabbit furnishing trimmings for coats and other articles of apparel, while gloves are manufactured from goat skin, dog skin, and many other varieties of small hides. WOOLLEN WASTE.—The uses found for the waste from various industries which depend upon raw material derived from animals are interesting. Thus, in the case of worn-out woollen goods the material called shoddy' is obtained. Then the worn-out shoddy reappears in the form of druggets for the floor. From raw wool itself a useful oil or grease is obtained, which is familiar under the name of lanoline, and the various liquors resulting from the washing of wool yield by suitable treatment valuable potash salts. Wool and similar animal products, such as horn and blood, can be roasted for the production of yellow prussiate of potash. ARTIFICIAL MANURES are produced from all kinds of animal refuse, such as the offal from slaughterhouses, stale fish, sewerage matter, in fact from almost every kind of decaying animal refuse.

Town Refuse. This consists of a very miscellaneous collection of animal, vegetable, and mineral refuse. In some towns a systematic course of treatment is adopted, whereby any refuse which has a commercial value is sorted out from that which is of no value. The former is sold to merchants and manufacturers, while the latter is usually burnt. An average collection of this kind will yield saleable waste paper, rags, bottles, old tins (from which the tin can be recovered), broken glass, which can be used over again, and finally a mixture of cinders and combustible matter, which is of value to brick manufacturers. In other towns the whole of the collected refuse is burnt in large special destructors, the heat given out by the furnaces being sufficient to supply a large amount of heat energy for town purposes, such as the production of electricity for lighting. At Hastings the steam produced in this manner is used in pumping sea water for flushing the sewers and for watering the streets. The use found for the waste products of industrial enterprise, as distinct from domestic refuse, is a monument to the ingenuity and skill of the men engaged in manufacture.

Vegetable Refuse. The foremost instance is the utilisation of the by-products in the manufacture of coal gas. These are more fully treated under the heading of GAS MANUFACTURE (*q.v.*) Mention may be made of sal ammoniac, spirits of hartshorn, sulphate of ammonia, obtained from gas liquor; benzol, nitrobenzol, carbolic acid, aniline, anthracene from coal tar, the two latter compounds being the source of the well-known coal-tar dyes. The final refuse in the gas retorts is the well-known domestic coke. PAPERMAKING finds use for such materials as old rags, old waste paper, straw, old rope, canvas and sails, jute and hemp bagging, all of which are eventually converted into paper, cardboard, or papier-maché. Many of the by-products obtained during the manufacture of paper can be treated and used over again by means of ingenious chemical operations. In the STARCH INDUSTRY many apparently useless materials find profitable employment. In the manufacture of starch from wheat a sticky plastic substance called gluten is produced, which is employed in calico printing. The pulpy refuse is usually mixed with other materials and converted into cattle food. In the SOAP INDUSTRY the recovery of glycerine as a by-product is an interesting instance of the value of technical research. The treatment of fats with alkali for the manufacture of soap (*q.v.*) gives a large proportion of waste lyes from which glycerine is made. Glycerine is used in great quantities for the production of explosives, and industries having no apparent connection with one another are sometimes closely related. In the TIMBER TRADE much ingenuity has been displayed in the utilisation of waste wood. Large quantities of sawdust are mixed with tarry matter and converted into briquettes for fuel. Dried sawdust is used for polishing small metal goods, which are placed in closed vessels and rotated, the polishing being effected by the friction of the goods with the sawdust. Artificial wood is prepared from sawdust by the use of certain binding mediums like glue mixed with bichromate of potash. Wood waste is largely employed in the manufacture of oxalic acid, produced by fusing the wood waste with caustic soda, and this is largely used in textile industries. It may also be employed for the manufacture of crude acetic acid, the dry distillation of wood waste yielding wood spirit, acetic acid, and wood charcoal.

Mineral Refuse. One of the most remarkable instances of the recovery of valuable material from waste is the recovery of sulphur from ALKALI WASTE. According to the Alkali Inspector's twenty-third report for the year 1886, 387,000 tons of waste were produced at Widnes and Runcorn. This would contain about 58,000 tons of sulphur, nearly the whole of which was lost. In 1888 Mr. A. M. Chance introduced an improved process, by means of which this enormous weight of material could be treated with carbonic acid gas liberating sulphuretted hydrogen, which on burning with a sufficient quantity of air deposited the pure sulphur in a solid form. Not only was the waste material thus effectually dealt with, but naturally the cost of production of the soda and alkali was sensibly reduced. The introduction of chemical methods of washing the slimes and residues from GOLD MINES has resulted in very marked economies. Many of the slimes and residues though containing a very minute percentage of gold can be chemically treated by means of cyanide compounds (*see* GOLD, CYANIDES, and GAS MANU-

FACTURE [C]). The gold and silver residues obtained by photographers are carefully preserved and treated for the recovery of the precious metals. In IRON WORKS the slag produced is employed for useful purposes. The slag obtained from blast furnace works is converted into slag wool by means of a current of steam, and this is used as a composition for covering boilers and steam pipes. The slag is also made into building stone and hard brick; and when ground up fine in a mortar and mixed with cement forms a useful concreting material.

Waste Weir (*Civil Eng.*) A weir in a reservoir for discharging the superfluous water in time of flood.

Watch and Clock Making. Clocks and watches are machines automatically recording the number of vibrations made by a pendulum, or, by its substitute in portable timepieces, a balance and spring.

The machine contains (1) the MOTIVE POWER, usually a raised weight or coiled spring; (2) a TRAIN OF WHEELS and pinions moving with different velocities to record various required intervals of time; (3) the ESCAPEMENT, an arrangement for periodically arresting the advance of the train, so that the tendency of the motive force to accelerate the speed shall be checked at frequent and regular intervals, and for conveying to the pendulum or balance sufficient impulse to restore the energy lost in overcoming the various resistances tending to bring those time measurers to rest.

The mechanism of a good timepiece is so accurately made and so well designed that it does what perhaps no other machine of any kind is expected to do—that is, it will go night and day for years without skilled attention. The wheels and pinions usually have epicycloidal teeth, but in some parts of turret clocks, in the keyless mechanism of watches, and other parts where very low numbered pinions are not required, involute teeth may be advantageously used; either kind properly employed ensures smooth working, and, even more important, a constant angular velocity throughout the whole phase of contact of each tooth. The pinions and the escapement staffs are of highly polished tempered steel, to resist wear and reduce the effect of friction. The reduced portions, or pivots, which work in the bearings, are as small in diameter as the necessary strength will allow, and the bearings are often jewelled.

The mechanism of the finest timepiece is subject to one source of trouble, which will probably always be a trouble. It is necessary to lubricate nearly all the rubbing surfaces, and jewelled bearings do not remove this necessity. The lubricant must not be too thin or likely to evaporate, it must not be too thick or likely to corrode, and however good it may be there is always a possibility of one extreme in course of time; especially as an oil that will keep good for a long time with one wearer, will dry up with another, and will thicken with yet another. Except for the lubrication trouble, the timepiece, as a machine, may be accepted as a very good specimen of the perfection of mechanism. The natural errors to which the pendulum and the balance and spring are subject will be dealt with later.

The standard by which all timepieces are ultimately checked is the "Sidereal Day," the uniform interval of time taken by the earth to make one exact rotation on its axis; but the standard interval recorded by most clocks and watches is the "Mean Solar Day," an interval equal to the *average length* of the "Apparent Solar Day." No two consecutive solar days are of precisely equal duration, so the mean of these continually varying intervals is used as the standard for all civil purposes.

In checking the rate of a clock by astronomical observations with the aid of a transit or other meridian instrument, it will often be found convenient to use the transits of the sun. These occur at irregular intervals, but the irregularities are accurately known, and are furnished in the "Nautical Almanac" years in advance; we therefore find it just as reliable to use the sun, and for checking the rate of a mean-time clock the necessary calculations are easier than those required for sidereal observations.

Whole days are determined and checked by astronomical observations. The subdivisions of the day cannot be so determined. In modern timepieces the subdivisions are measured either by the oscillations of a pendulum or by the vibrations of a balance attached to an elastic spring.

The discovery of the isochronism of pendulum vibrations made it possible to subdivide the day with great accuracy. The time of vibration depends upon the length of the pendulum and is proportional to the square root of the length.

$$\tau = \pi\sqrt{\frac{l}{g}}$$

is the usual formula denoting the time of one complete swing in one direction; τ being the time in seconds, π the ratio of circumference to diameter, approximately 3·1416, l the length of the pendulum, and g the acceleration due to gravitation. "g" has different values at different parts of the earth's surface, but so long as the length of the pendulum does not alter, the time of vibration at any one place will be almost perfectly constant. A clock controlled by a pendulum is probably the most accurate of all timekeepers. The pendulum should not be shorter than a "seconds" pendulum = about 39·14 in. It, and the mechanism, should be rigidly supported, and a weight should be used to drive it, as the energy of impulse will then be sensibly constant. We find, however, that if the machine be mechanically perfect there are, at least, three sources of error to which the pendulum is liable—change in the amplitude of the arc described may cause a "circular error," change in the atmospheric pressure may cause a "barometric error," and change of temperature may cause a "temperature error."

If a pendulum is describing large arcs of vibration, and the arcs vary much in amplitude, there will be a circular error, as large arcs take *slightly* longer than small ones; but in clocks of precision the largest arc permitted is small, seldom more than 2° from the point of rest, and every effort is made to maintain the amplitude constant, so that the isochronism in a good clock is but little disturbed by the circular error.

The barometric error is due to changes in the atmospheric pressure: when the pressure increases, the pendulum meets with greater resistance to its progress and the clock loses. The error is small, estimated at about 1 second per day for a change of 3 inches in the barometric reading, but in very fine clocks some provision is made to counteract it. In the Greenwich sidereal clock a barometer tube is fitted inside the clock case; the rise and fall of the mercury in the open end of the tube cause a horseshoe magnet to recede from, or approach, two bar magnets fixed to the front and back of the pendulum bob, thus reinforcing the acceleration due to gravity,

more or less, according to the nearness together of the horseshoe and the pendulum magnets. The horseshoe is adjusted under the pendulum magnets with the unlike attracting poles opposite one another. For the new physical laboratory at Bushey House a clock has been made with an airtight case, an air pump is attached, the pressure will be reduced below the normal and maintained constant, so that no variation may arise from this cause.

The largest variation to which an ordinary pendulum is subject is due to the temperature error. Nearly all materials undergo changes of dimensions when the thermometer alters. An iron, or steel, or brass rod becomes longer in heat and goes slower, so that all good clocks require compensation pendulums. In all such pendulums two or more materials are used, having very different coefficients of expansion. The rod being of the material with a small expansion, the other parts are so arranged that just as much as the change in the rod tends to displace the centre of oscillation, the other part tends to move it in the opposite direction, and the effective length of the pendulum remains constant in all temperatures.

A mercurial pendulum has a rod of steel, and the bob is a jar of glass, or of steel, containing mercury. As mercury expands and contracts very much more than steel for the same change of temperature, we find that about 6 in. of mercury is sufficient to keep the centre of oscillation of a seconds pendulum at a constant distance from the suspension, and so compensate the temperature error.

A zinc and steel pendulum has a rod of steel; on the rating nut at the bottom rests a zinc tube, from the top of the zinc tube hangs a steel tube terminating in a collar on which the bob is supported *at its centre*, so that the expansion and contraction of the bob shall have little effect on the time. As the coefficient of expansion of zinc to that of steel is in about the proportion of 8 to 3, we find that a tube of zinc about 24 in. long is sufficient to compensate a seconds pendulum. The length of steel rod + the length of steel tube must be to the length of zinc tube *inversely* as the respective coefficients of expansion.

The recent experiments of Dr. Guillaume with alloys of nickel and steel, in different proportions, have produced some remarkable results. It is stated that at least one specimen has been produced having no expansion at all. There may be some doubt if so desirable a result can be repeated, but there is no doubt that many specimens of nickel steel have been obtained possessing exceedingly small coefficients. As with most alloys, the result of a melt is more or less uncertain; each individual rod should be tested, and a rather long process of annealing has to be undergone to make the metal workable, and to ensure its retaining its peculiar properties. Its use for pendulum rods is still in the experimental stage, but it promises to be a very valuable discovery for such a purpose, and as the clock at Bushey House, already referred to, has one of these rods for which a very short brass tube is sufficient to compensate it, the record of its performance will be looked forward to with great interest.

A pendulum cannot be used for a portable timekeeper, a BALANCE and SPRING taking its place in chronometers, watches, and carriage clocks. The balance is a flywheel, storing up the energy received at each impulse, thus being enabled in its return vibration to unlock the escapement, to allow the train of wheels and the hands to advance, and to receive fresh impulse. It is highly important that the balance shall be truly a "balance"—*i.e.*, that the staff on which it is mounted shall be accurately in the centre of the mass. If it be the least out of weight, or "out of poise," as it is called, the rate in the different vertical positions of the watch will vary; the balance will no longer be a "balance."

The regularity of the vibrations of a balance is due to the controlling influence of the spring. This is an elastic spring fixed at one end, the other end being attached to the balance near its axis. There is no circular error as with the pendulum. If the size and weight of the balance be suitably adapted to the energy of the motive power, and the spring is properly applied and adjusted, the arc of vibration may vary very much without any important change in the rate of vibration. If, owing to variation in the energy of impulse, the balance at one time travels twice as far as at another, it will travel twice as fast, and the time of vibration will be the same. The regularity of vibration is liable to disturbance by the varying effect of friction, and to the fact that the connection with the escapement has a greater retarding effect when the vibrations are small and the velocity slow, than when the arcs described are large and the speed of the balance rapid; but the modern timer is able to surmount these difficulties and obtains almost perfect isochronism. So much has been accomplished in this direction that the fusee, as a necessary equaliser of the motive power, has almost disappeared from the modern watch in favour of the going barrel, with its much simpler form of keyless mechanism.

The motion of the balance is affected, like that of the pendulum, by variation in the atmospheric pressure. Recent experiments indicate that the barometric error in a large watch is about 50 per cent. greater than the barometric error of a pendulum, that the error in a marine chronometer is a little less than that in a deck watch, while the error in small watches is slightly greater. There is at present no known method of correcting this, except by introducing centrifugal or isochronal errors, either of which might do more harm than good.

The time of vibration of a balance depends upon its "moment of inertia" (*q.v.*), and upon the elasticity and dimensions of the spring. As the elasticity of a spring of steel, and probably of any material suitable for balance springs, is very much affected by changes of temperature, we find that the temperature error of an uncompensated watch is far greater than that of a pendulum clock. When the temperature rises the diameter of the balance increases, its moment of inertia is greater, and this tends to make the watch lose. All the dimensions of the spring increase, it becomes longer, tending to make the watch lose, but in the same degree it becomes wider, tending to cause a gain; and for all changes of temperature the alterations in these two dimensions alone neutralise one another. It also becomes thicker, and this change of itself probably more than neutralises the increase in the diameter of the balance, so that the whole of the observed error is due to the change in the elastic nature of the spring.

The COMPENSATION BALANCE is designed to correct this error: it becomes smaller in heat, and larger in cold. In the ordinary form of compensation balance a steel disc is turned perfectly true. This is placed in a crucible containing molten brass. When cool the brass adheres, and is turned true, leaving a ring of brass outside the steel. The steel is recessed and cut away until only an inner ring of steel is left with a thin crossbar of the same piece of metal, in which the staff is fixed. A number of holes are drilled and

tapped through the bi-metallic ring; in these holes a less number of weights, usually gold screws, may be placed in different positions. The ring is cut right through in two opposite points, usually close to the crossbar, leaving each half of the ring fixed to the bar at one end, and quite free to move inwards or outwards at the other end. When the temperature rises the brass expands more than the steel, and the two metals, to remain together, must bend into a quicker curve, carrying the free ends of the rim in towards the centre. When the temperature falls the brass contracts more than the steel and flattens the curve, bringing the free ends outwards. How far the changes of curvature will affect the moment of inertia of the balance depends, in a great measure, upon how much of the movable weight is collected near the free ends of the rim. The final positions of the adjustable weights can only be determined by trial.

The thickness of the rim is dictated by experience. If too thick the weights are relatively light, their change of position has insufficient effect, and it may be necessary to substitute platinum screws for the gold ones at the free ends. If too thin there will be a centrifugal effect, greatest in the large arcs of vibration, tending to open the rims outwards, especially if much of the weight has to be collected near the free ends.

The proportion of brass to steel is an unsettled question. Some authorities have stated that they should be inversely as the respective modulus of elasticity. Others say inversely as the square roots of their elasticities. As the bending moment of an elastic bar of rectangular section is proportional to the *cube* of its thickness, it is possible that the thicknesses should be inversely as the cube roots of the respective elasticities. The two metals will then offer equal resistances to change of curvature.

The balance of a MARINE CHRONOMETER, instead of having gold screws round the rim as in watches, has two heavy brass weights grooved to fit the rim; these are held in position by pinching screws.

The compensation of a balance is not so perfect as that of a pendulum. With the latter it is only necessary that its length shall remain constant. The balance has to correct the errors due to changes in the elasticity of the spring, its effective radius must grow less in heat, and greater in cold. The change in the elasticity of the spring is, at least approximately, proportional to the change in the temperature; but the moment of inertia of the balance is proportional to the *square* of its radius of gyration, so that any balance changing its radius uniformly with the temperature is imperfectly compensated. It may be adjusted correctly for any two given temperatures, but the change in its moment of inertia will then cause it to gain at intermediate temperatures, and lose above or below the selected temperatures. In marine chronometers the error, which is never large, is in some cases reduced by adjusting the primary compensation for a narrower range of temperature than the total change it is to be adjusted for. The middle gain will then be less than if adjusted for a wider range. At the extremity of the selected range a supplementary or secondary compensation piece, called an "auxiliary," comes into action, and continues the compensation through a further limited change of temperature.

In NON-MAGNETISABLE WATCHES the balance spring, as well as the quick moving parts of the escapement, must be of other material than steel. The most successful of these springs are made of an alloy of palladium. For the lever, pallet, body, and roller aluminium bronze is one of the best materials.

T. D. W.

Water (*Chem.*) H_2O. A faintly blue coloured liquid, the blue colour only being apparent when a column of 2 metres or so is looked through; melts at 0° under a pressure of 1 atmosphere, or at 0·0076 under a pressure of water vapour equal to that of a column of mercury 4·66 mm. in height—that is, the melting point is raised or lowered by about 0·0075° for a decrease or increase respectively of 1 atmosphere pressure. Water is easily supercooled, so that if kept still and protected from dust it can be cooled far below its melting point without freezing; its vapour pressure at −10°, 0°, 15°, 100°, and 144° is respectively 2·1, 4·6, 12·7, 760, and 3040 in millimetres of mercury, from which it is seen that ice is markedly volatile and that water boils at 0°, 15°, 100°, or 144°, when the pressure is 4·6, 12·7, 760, and 3040 mm. of mercury respectively. When water freezes it increases in volume by about one-eleventh part, so that pipes and vessels containing water are often burst when water freezes in them. If the freezing is effected in a test tube immersed in a freezing mixture, the water is seen to crystallise in slender needles, but in snow the small crystals are united to one another, forming very beautiful six-sided geometrical figures—snow crystals. The latent heat of fusion of ice is 79 calories per gram; the latent heat of evaporation of water at 100° is 536 calories per gram. At 4° 1 cc. of water weighs 1 gram; this is the definition of the gram, the temperature of 4° being selected because water was believed to have its maximum density at this temperature. The real point of maximum density of water is 3·945°, that is, whether water is cooled below or heated above this temperature it expands: for example, 1 c.c. of water at 4° becomes 1·000122 c.c. at 0°, 1·000118 c.c. at 8°, 1·000997 c.c. at 16°. The specific heat of water at 15° is unity; it varies with the temperature. The refractive index for the D line is 1·3335 at 18°; it varies with the temperature. Water is a bad conductor of heat and electricity; for heat its conductivity is 0·00154 ($cm.^2/sec.$); for electricity it is $0{\cdot}04 \times 10^{-10}$ reciprocal ohm centimetres and referred to mercury as unit at 18° in the case of the purest water ever obtained; while for absolutely pure water it would probably be $0{\cdot}036 \times 10^{-10}$. (See below.) The conductivity for electricity increases with the temperature. The vapour of water has a density corresponding to the formula H_2O; but in the liquid state the molecules are almost certainly associated. An association of simple molecules of water to form more complex molecules would explain a number of the peculiar thermal properties of water; thus it has been assumed that water at 0° contains the two kinds of molecules $(H_2O)_3$ and $(H_2O)_2$—trihydrol and dihydrol. The high latent heat of fusion of ice, and its high specific heat, are probably due to the circumstance that much heat is required to resolve the trihydrol molecules into the simpler dihydrol molecules, while the high latent heat of evaporation may be due to the circumstance that a further large amount of heat is required to change the dihydrol molecules into single molecules, for steam consists, as its vapour density shows, of single molecules. Now Ramsay and Shields have shown, from the molecular surface energy of water, that at 5° water has a molecular weight of between 3×18 and 4×18. Water is resolved into its elements when heated to a high temperature; dis-

sociation begins at about 950° and is complete at something over 2500°; it is also decomposed when electric sparks are passed through its vapour. Chemically, water is at the same time a weak acid and a weak base; this is shown by adding water to some water containing phenol phthalein rendered pink by a drop of dilute caustic soda solution, when the colour will be removed, and by adding water to some water containing methyl orange rendered pink by a drop of dilute sulphuric acid, when the colour will be changed to yellow. From the electrical conductivity of pure water it has been calculated that 1,000,000 litres at 18° contain 0·08 gram hydrogen and 1·33 gram hydroxyl ions; yet small as the amount of ionisation is it corresponds to some millions of hydrogen ions in each cubic millimetre of water. This ionisation of water enables us to explain the behaviour of (1) salts formed by the union of a weak base with a strong acid, (2) salts formed by the union of a strong base with a weak acid in dilute aqueous solution. For example, (1) a solution of ferric chloride has an acid reaction and at great dilution ceases to show the ordinary reactions of the ferric ion; but if some hydrochloric acid is added to the liquid, it will again show the reactions for the ferric ion—

$$\overset{3+}{Fe} + 3\overset{-}{Cl} + 3\overset{+}{H} + 3\overset{-}{OH} = \underbrace{Fe(OH)_3}_{\text{Colloidal ferric hydroxide.}} + 3\overset{-}{Cl} + 3\overset{+}{H}$$

—excess of hydrochloric acid reconverts the hydroxide into chloride. (2) Potassium cyanide solutions are alkaline and smell of prussic acid.

$$\overset{+}{K} + \overset{-}{CN} + \overset{+}{H} + \overset{-}{OH} = \overset{+}{K} + \overset{-}{OH} + HCN$$

The presence of water often causes reactions to occur which will not occur in its absence, as the burning of phosphorus in oxygen, the union of hydrogen and oxygen or chlorine, the dissociation of ammonium and mercurous chlorides, and others. Many metals decompose water: sodium, potassium, calcium, barium at the ordinary temperature; iron, zinc, magnesium only on heating; in all these cases hydrogen is liberated and the hydroxide of the metal formed, or if the hydroxide is not stable at a high temperature the oxide is formed. The halogens decompose water, the speed of the decomposition decreasing with the atomic weight of the halogen. For the action of carbon *see* WATER GAS. Water reacts with basic oxides to form alkaline hydroxides, and with many non-metallic oxides and the highest oxides of some metals to form acid hydroxides (acids). It also unites with many salts, as what is called water of crystallisation, thus $CaCl_2 6H_2O$, $CuSO_4 5H_2O$, $FeSO_4 7H_2O$, $K_4Fe(CN)_6 3H_2O$, and a vast number more. The last three whose formulæ are given are coloured blue, green, and yellow respectively, but the anhydrous salts are all white; so that some coloured salts owe their colour to their water of crystallisation. It is worthy of note that many salts which crystallise with water of crystallisation have in this state a volume equal to that of the water they contain when in the form of ice—*e.g.* the gram molecule, $Na_2CO_3 10H_2O$, has the same volume as $10H_2O$ in the form of ice. *See also* WERNER'S THEORY. For the behaviour of water as a solvent, *see* SOLUTIONS. Water is produced when hydrogen burns in oxygen or air; in this reaction hydrogen peroxide is first formed, either wholly or in part, and this is decomposed at the high temperature into water and oxygen. The production of hydrogen peroxide is shown by directing the flame of hydrogen burning in air against ice, and testing the melted ice for the peroxide. Water is also formed when compounds of hydrogen burn in air or oxygen—*e.g.* when ammonia burns in oxygen, and coal gas in air; it is also formed when an acid acts on an oxide, hydroxide, or carbonate. In the formation of water from its elements much heat is evolved; the production of 18 grams of water at 18° from its elements evolves 67·9 large calories (1 large calorie = 1000 small calories). When hydrogen and oxygen are mixed in the right proportions to form water, and a light applied, the union is very rapid (in *long* tubes it occurs at about the speed of sound), and it is this sudden evolution of a large amount of heat that is responsible for the explosion which occurs. The composition of water by weight has been determined in several ways. Professor Morley proceeded as follows: ". . . A quantity of hydrogen was weighed while absorbed in palladium, a quantity of oxygen was weighed in a globe, the two were combined, and the water produced was weighed. The two gases were brought together at two platinum jets enclosed in a small glass apparatus, which was weighed while exhausted, where they were made to combine. When the combustion was ended, the gas remaining in this combustion apparatus and the connecting tubes was extracted with a Töpler air pump, measured and analysed. The combustion tube, the globe which had contained oxygen, and the palladium tube were weighed again. From the amounts of oxygen and hydrogen extracted were subtracted the amounts of the gases found in the analysis; the remainders were the quantities combined in the combustion apparatus. . . . The amount of water produced was measured by the gain in weight of the combustion apparatus. . . . The volume of hydrogen used in most of the experiments was forty-two or forty-three litres; the amount of water produced was about thirty-four grammes in each experiment; twelve successful experiments were made. The amount of gas left unburned, and therefore measured in the endiometer, varied from a six-hundredth to a ten-thousandth of the quantity concerned." The mean result is 2 parts by weight of hydrogen to 15·879 parts by weight of oxygen. The determination of the composition of water by volume has been made by exploding large quantities of oxygen and hydrogen in small known quantities at a time, and determining the composition of the residue at the end. At 15° one volume of oxygen unites with 2·00245 volumes of hydrogen (Scott).

Natural waters are never pure. When pure water is required in the laboratory, ordinary tap water is distilled. Water which has been distilled from tap water is pure enough for most purposes, but if required quite free from ammonia and organic matter and minute traces of substances carried over by spirting, special measures must be taken. To get water free from ammonia, some potassium hydrogen sulphate may be added to the water before distilling; to get it free from organic matter and ammonia, the water must be boiled for some hours, in a flask provided with a reflux condenser, with potassium permanganate and caustic potash, then distilled. The first portions of the distillate will contain ammonia, but the succeeding portions will be free. The distillation must not be continued too far, or contamination from spirting results. Very pure water can be obtained by the apparatus shown in the figures. Fig. 1 shows the complete apparatus. Fig. 2 shows the still,

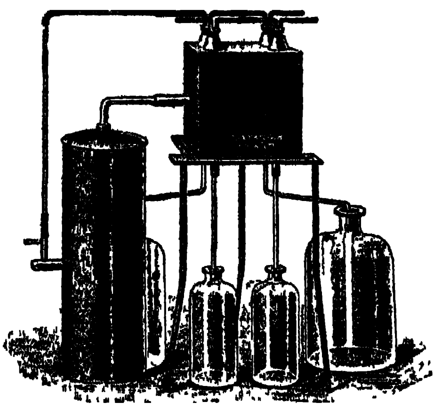


FIG. 1.

which is provided with a constant level arrangement B, F, an opening for cleaning, A, baffle plates starting at D to prevent spirting, and a cover, E, to prevent loss of heat; the arrows show the direction taken by the steam. Fig. 3 shows the condensing arrangement, which is a copper box, into the top of which four glass tubes are let, each provided with inlet and delivery tubes for condensing water; below each tube is a funnel-shaped tube which collects the water and delivers it into a bottle placed below, the side tube brings in the steam; tube 5 carries away the water which condenses on the metal of the condenser. A rapid stream of cold water passes through tubes 1 and 2, a slow stream through 3 and 4—this also feeds the still. Tubes 1 and 2 give the best water, and tube 5 gives the worst. Water having a conductivity of one reciprocal megohm can be obtained from tubes 1 and 2 by adding a little potassium hydrogen sulphate to the water in the still, and by boiling this water in a platinum vessel its conductivity is reduced by half, when it has a conductivity ten times that given above for the purest

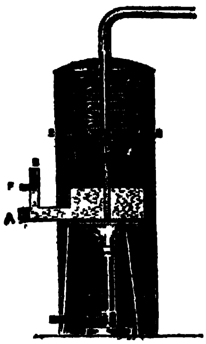

FIG. 2.

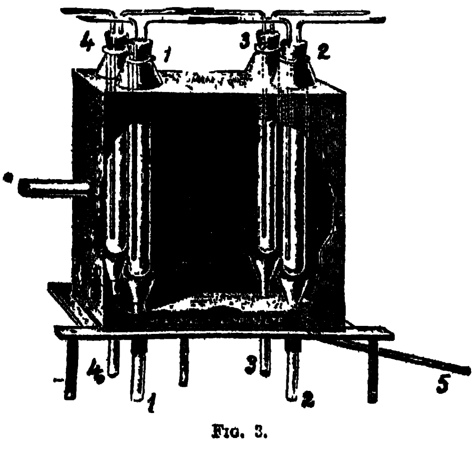

FIG. 3.

water yet obtained. This purest water was obtained by Kohlrausch and Heydweiler, who distilled water in a glass vessel under a pressure of 0·01 mm. mercury; the glass vessel employed had been in constant use for ten years, so that the soluble portions of the glass had been practically all removed (they say they only obtained the above result with one out of a series of vessels which they used). In such water the impurity is about 1 part in 100,000,000 parts, or about 10,000 times less than the weight of the gases the water could absorb from the atmosphere.

On the large scale, for drinking purposes, water is purified by filtration (*q.v.*) *See also* SANITATION. Of the ordinary natural waters, rain water is the purest, and contains on an average about 2 to 3 parts of dissolved solids in 100,000. It contains the gases which it has washed out of the atmosphere, and traces of solids such as common salt. In towns it invariably contains sulphuric acid, and products from the incomplete combustion of coal. Spring and river waters owe their impurities to the ground through which they have passed; thus an average spring or river water will contain about 30 parts of dissolved solids in 100,000. Many spring waters have medicinal properties, for example, those at Harrogate (sulphur wells), which contains sulphuretted hydrogen, and magnesium sulphate and chloride; at Woodhall, which contains sodium bromide and iodide, and much carbonic acid; at Homburg, which contains bicarbonate of iron, lithium chloride, sodium bromide and traces of iodide, and much common salt and magnesium chloride; at Vichy, which contains very large quantities of the bicarbonates of sodium, calcium, and magnesium; at Hunyádi János, which contains very large quantities of magnesium and sodium sulphates. Sea water contains about 3,900 parts of dissolved solids in 100,000 parts. The solids consist of the chlorides, sulphates, bromides, iodides of sodium, magnesium, potassium, calcium, and lithium, the iodine and lithium being present in minute amount only. Waters used for washing purposes are classified as hard and soft. These terms relate to the action of the water on soap; a water which yields a lather with difficulty is called hard. To explain the action of a hard water on soap, we shall suppose that soap is sodium stearate, $NaC_{18}H_{35}O_2$. Soluble salts of calcium and magnesium act on soap thus:

$$CaSO_4 + 2NaC_{18}H_{35}O_2 = \underbrace{Ca(C_{18}H_{35}O_2)_2}_{\text{Calcium stearate.}} + Na_2SO_4$$

Now calcium and magnesium stearates being insoluble in water, separate as solids, and this goes on until all the calcium and magnesium salts present in the water are removed as calcium and magnesium stearates, after which the soap begins to dissolve in the water and produces a lather. Thus the harder the water is, the more soap will it require before a lather can be formed. The four salts which commonly cause water to be hard are the acid carbonates and the sulphates of calcium and magnesium. When water containing the acid carbonates of these metals in solution is either boiled or treated with milk of lime (*see* CALCIUM COMPOUNDS), they are converted into the normal carbonates, which are nearly insoluble in water:

$$Ca(HCO_3)_2 = CaCO_3 + H_2O + CO_2$$
$$Ca(HCO_3)_2 + Ca(OH)_2 = 2CaCO_3 + 2H_2O.$$

That is, the hardness due to the acid carbonates is removed; this kind of hardness is therefore called Temporary Hardness. The sulphates of calcium and magnesium cannot be removed by boiling, and lime

water has no action on calcium sulphate, while it would only replace magnesium sulphate by its equivalent of calcium sulphate. The hardness due to the sulphates (and chlorides if present) of these metals is therefore called Permanent Hardness. Both temporary and permanent hardness can be nearly completely removed by the addition of both milk of lime and caustic soda in proportions determined on after analysis:

$$Ca(HCO_3)_2 + CaSO_4 + 2NaOH = 2CaCO_3 + Na_2SO_4 + 2H_2O,$$

excess of acid calcium carbonate being removed by the milk of lime. Natural waters such as spring, well, and river water are often contaminated by drainage from cultivated land and by the addition of sewage. Such waters contain organic matter and the products of its decomposition, such as ammonia, nitrites, nitrates, and sodium chloride (from urine). The ammonia in such water is estimated by making it alkaline, distilling over the ammonia, and comparing the colour given to the distillate on adding Nessler's Reagent, with that produced by the same reagent in known amounts of ammonia. An idea of the organic matter can be obtained by distilling the residue from the last distillation with alkaline potassium permanganate, when a portion of the organic nitrogen is converted into ammonia, which distils over and is estimated as before; also the water is treated with potassium permanganate and sulphuric acid, when the organic matter is oxidised—in an analysis these last two results are returned as albuminoid ammonia and oxygen absorbed respectively. The nitrites are estimated by the depth of colour they produce in an acidified solution of meta-phenylene diamine (*see* BISMARCK BROWN); and the nitrates are reduced to ammonia by a zinc-copper couple and the ammonia is distilled over and estimated as before—the nitrites and nitrates are returned as nitrogen. A water for drinking purposes should not contain in 100,000 parts over ·005 parts ammonia, ·01 parts albuminoid ammonia, ·1 part oxygen absorbed in one hour, about ·2 parts of nitrate expressed as nitrogen, 2 parts of total chlorine; it should contain no nitrite. But these numbers are all subject to allowances for the source of the water. A drinking water should always be examined bacteriologically as well as chemically.

W. H. H.

Water Bar (*Build.*) A longitudinal bar of metal let into a groove between the wood and stone sills of a window to prevent water from penetrating the joint.

Water Battery (*Elect.*) A series of simple cells having copper and zinc plates immersed in water. It is chiefly useful in the calibration of electrometers.

Water Colour Painting. *See* PAINTING.

Water Cooled. A term applied to machinery or apparatus which is surrounded by a space in or through which water flows, to carry off heat and so prevent undue rise of temperature. The cylinder of a gas engine, etc., is commonly water cooled. *See* PETROL ENGINE, *p.* 514.

Watered Tabby (*Silk Manufac.*) Plain silk woven as tabby (*q.v.*) a coarse weft being used. The watered effect is obtained by pressure between rollers.

Water Gas (*Chem.*) A mixture of hydrogen (about 50 per cent.), carbon monoxide (about 40 per cent.), carbon dioxide (about 3 per cent.), methane (about 0·5 per cent.), nitrogen (about 4 per cent.), and traces of other gases, especially sulphuretted hydrogen, the mixture being produced by blowing steam over fuel such as coke heated to a sufficiently high temperature. Many forms of apparatus are in use for the manufacture of water gas, particularly in the United States of America, where it is used on an enormous scale. The method of working is as follows:—Air is drawn over burning coal or coke by an exhausting pump, the gas from the burning fuel is led over brickwork, which is thereby heated to a high temperature, and it may then be used to heat a boiler: this gas is producer gas, and is combustible, but has not the same value as water gas as a calorific agent; it is utilised if possible. When the brickwork and fuel are hot enough, steam is blown through the heated brickwork and then over the fuel; the gas so produced is water gas, and it is sent to gas holders. The reaction between the steam and coal is strongly endothermic, so that the temperature of the fuel falls: when it has fallen low enough air is drawn over the fuel again, and so on. The principal reactions are

$$C + H_2O = CO + H_2$$
$$C + 2H_2O = CO_2 + 2H_2.$$

The former absorbs 27,700 small calories, the latter 17,160. At 1,000° the former reaction occurs almost to the exclusion of the latter, but at 600° the reverse is the case; but even at the higher temperature excess of steam must not be used, or it will react with the carbon monoxide, forming the dioxide and hydrogen.

Water gas burns with a blue flame; it requires about half as much air for its combustion as coal gas does: its "calorific power" is about half that of coal gas: in British Thermal Units it amounts to about 300. ("Calorific power"=the number of British Thermal Units evolved by the combustion of 1 cubic foot of the gas. The B.T.U. is the heat required to raise 1 pound of water from 60° F. to 61° F. =252 calories). Water gas is extremely poisonous on account of its large percentage of carbon monoxide and as the gas has practically no smell the use of the pure gas is not free from danger. In 1889 two workmen employed at the Leeds Forge Works were poisoned by the gas in a cabin—a cooking stove supplied by the gas had been turned on and not lighted; and two days afterwards several medical men performing the post-mortem in a room containing some gas burners partly turned on but unlighted, experienced symptoms of carbon-monoxide poisoning.

Water gas having no illuminating power can only be used for heating purposes, or with a Welsbach or similar mantle for illuminating purposes. When required to be used for lighting as well as for heating purposes it is "carburetted"—that is, mixed with oil gas and heated to a high temperature, whereby hydrocarbons that burn with a luminous flame are added to the gas. W. H. H.

To enable an escape of the gas to be easily detected, a small quantity of a vapour having a pronounced smell is sometimes added to it—a trace of carbon disulphide serves the purpose.

Water Glass (*Chem.*) *See* SOLUBLE GLASS *and* SODIUM COMPOUNDS.

Water Glass Painting. *See* PAINTING.

Water Joint (*Build.*) A device used in jointing stone cornices, etc. A ridge is formed on each side of the joint on the top surface, to throw off the rain and prevent it getting into the joint.

Water Lock. A WATER SEAL (*q.v.*).

Watermark (*Paper Manufac.*) The transparent name or pattern produced in paper by the "dandy roll" or other means.

Water Meters. There are two principal kinds of water meter, the most accurate type being the POSITIVE METER, in which the whole of the water supplied passes through a cylinder fitted with a piston whose movements are recorded by suitable mechanism. For large supplies a TURBINE METER is used, in which a small water turbine (*q.v.*) is driven by the current of water, and the revolutions of the turbine recorded by mechanism. From this the amount of water which has flowed through the meter may be found.

Waterproof (*Woollen or Worsted Manufac.*) A cloth which has been chemically treated to make it impervious to wet. *See also under* RUBBER.

Waterproof Paper. The Willesden paper consists of ordinary paper passed through a bath of cupro-ammonium (a solution of copper in ammonia).

Water Seal (*Plumb*). *See* SEAL *and* SANITATION (SEWERAGE AND DRAINAGE), *p.* 638.

Waterspout (*Meteorol*). Cloud brought down to the land or water surface by a rapid gyrating motion like that which takes place near the centre of a tornado. When occurring over a water surface, the level of this surface is slightly raised.

Water Supply. *See* SANITATION, *p.* 636.

Water Twist (*Cotton Manufac.*) A noted strong, round and uniform yarn, spun on the flyer or throstle frame. Originally spun on Arkwright's water frame.

Water Waste Preventer (*Sanitation*). A flushing apparatus which serves to break the connection between the water supply pipe and the water closet. The most ordinary forms in use are the "valve cistern" and the "siphon waste preventer." In the former water only flows so long as the chain is held. It is open to objection, as the cistern is liable not to to be completely emptied. In the siphon waste preventer one pull of the chain is sufficient to put the siphon in action and discharge the entire contents of the cistern. Water waste preventers should be fixed at a height of not less than 4 feet above the basin in order to secure a proper flush, and should contain not less than 2 gallons of water, the service pipe being 1¼ or 1½ inches in diameter.

Water Way (*Plumb.*) The aperture through a cock or valve when open.

Watt (*Elect.*) The unit of power in ordinary electrical practice. It is the energy furnished in 1 second by a current of 1 ampère flowing under a potential difference of 1 volt—*i.e.* 1 JOULE (*q.v.*)—per second. One horse power (*q.v.*) equals 746 watts.

Watt Hour (*Elect. Eng.*) A unit of supply of electrical energy, being a supply of 1 watt for 1 hour. The commercial unit is 1,000 watt hours, and is known as 1 Board of Trade Unit (1 B.T.U.)

Wattless Current (*Elect.*) The number of watts supplied by an alternating current whose virtual value is $\bar{C}$, virtual voltage $\bar{E}$, and angle of lag ϕ, is $\bar{C}\bar{E} \cos \phi$. If the current be regarded as resolved into two components, one being $\bar{C} \cos \phi$ which is in phase with the volts, and may be termed the WORKING CURRENT, and the other $\bar{C} \sin \phi$, which differs in phase from the volts by 90°, and contributes nothing to the watts, then this second component is the WATTLESS CURRENT.

Wattmeter (*Elect. Eng.*) An instrument for measuring the power supplied to any electric circuit; in direct current circuits this is the simple product of the current in ampères, by the voltage. For alternating current circuits it is $\bar{C}\bar{E} \cos \phi$, where $\bar{C}$ and $\bar{E}$ are the virtual current and virtual voltage, and ϕ the angle of lag.

Watt's Indicator and Indicator Diagram (*Eng.*) *See* INDICATOR, etc.

Wavellite (*Min.*) Hydrous phosphate of alumina; orthorhombic, usually in small spheres having a radial structure; nearly perfect cleavage; colour white to brownish. Found in Devon and Cornwall, Scotland, Ireland, Central Europe, United States.

Wave Moulding (*Architect*). A moulding very freely used in decorated Gothic work. It consists of two ogee (*q.v.*) mouldings, forming a hollow with a swelling in the centre.

Waves and Wave Motion (*Phys.*) A wave is a periodic disturbance which is passed on continuously from one part of a medium to the next. The disturbance or motion of the individual particles of the medium may take different forms. In water waves, in a vibrating string, and in light waves, it is at right angles to the direction of propagation of the wave; such disturbances are termed TRANSVERSE WAVES. In the transmission of sound through air, the disturbance occurs in the same direction as the propagation: the disturbances are termed LONGITUDINAL WAVES. The velocity of a wave is the rate at which the disturbance travels. Generally speaking, if E be the elasticity of the medium, and ρ its density, the velocity V is—

$$\sqrt{\frac{E}{\rho}}$$

Here E is the particular modulus of elasticity concerned in the propagation. For a sound wave in a gas it is the volume elasticity, for a longitudinal wave in a solid rod it is Young's modulus, and for a torsional wave it is the simple rigidity. For a cord or string whose mass per unit length is m, and which is stretched with a tension T, the velocity of a transverse impulse is—

$$V = \sqrt{\frac{T}{m}}$$

The WAVE LENGTH is the distance from any given particle in the medium, to the next particle whose displacement and motion are similar. In water waves, for example, it is the distance from crest to crest, or hollow to hollow. If n be the frequency of the waves, *i.e.* the number which are produced, or which pass a given point, in unit time, and if V be the velocity and λ the wave length, then $V = n\lambda$.

A WAVE FRONT is a surface (or line) drawn through particles of the medium which are in the same phase of vibration. If the waves be in two dimensions, as in the case of water waves, the surface becomes a line; thus if a stone be dropped into still water, the waves travel outward from the point of disturbance, and the wave fronts are circles, made readily visible by the successive crests and troughs. Waves may be described according to the geometrical form of the wave front; *e.g.* a SPHERICAL WAVE, such as travels through free air from a sounding body, a PLANE WAVE, etc.

A line coinciding with the direction of propagation

of the disturbance is termed a RAY. In the case mentioned, the rays are actual radii of the circles, and obviously at right angles to the wave front.

Waves, Electric (*Phys.*) When an oscillatory discharge (*q.v.*) occurs, a portion of the energy is given off from the circuit and sets up in the surrounding medium the form of radiation known as Electric Waves, which closely resemble light and heat waves in their physical properties. *See* RADIATION, *p.* 591.

Electric waves are usually produced by the passage of a spark between two polished metal balls, which are charged up to a high difference of potential by means of an induction coil. The frequency of the waves is the same as that of the oscillatory discharge, and therefore varies according to the self-induction, resistance, and capacity of the circuit in which the discharge occurs. Waves so produced are detected in several ways, of which the most important are the RESONATOR and the COHERER. The Resonator consists of a simple circuit, usually of thick wire carrying metal balls at its ends, which are bent round till they nearly meet, and so form a narrow spark gap. If the resonator be correctly "tuned" or adjusted in size, the presence of electric waves can be detected by sparks produced between the metal balls. The Coherer consists of a small tube containing metal filings, included in series with a galvanometer and a cell, or with a delicate relay actuating ordinary telegraphic instruments. The normal resistance of the filings is so great that no appreciable current flows in the circuit, but directly electric waves impinge on the coherer it becomes a conductor, and a current flows through the galvanometer, producing a readable deflection. If the coherer be now tapped lightly it returns to its former condition, and the current stops.

Electric waves can be reflected by plane or curved mirrors, and brought to a focus by the latter. They can be refracted (Hertz used prisms made of pitch for this purpose), and they can be polarised. Measurements can be made of their wave length and their velocity, which latter is found to correspond very closely with that of light.

Wave Theory (*Phys.*) The theory which explains the phenomena of light and other forms of radiant energy by the formation of waves through an invisible medium, the ETHER, which fills all space. The WAVE *or* UNDULATORY THEORY superseded the earlier CORPUSCULAR *or* EMISSION THEORY, (which assumed that a luminous body emitted small particles which travelled through space at a high velocity), and furnishes an explanation of all known phenomena of the nature of light.

Wavy (*Her.*) A bar, bend, or other ordinary (*q.v.*) may be represented "wavy" or curved with three undulations. Wavy or undée is also one of the forms of partition lines. *See* HERALDRY.

Wavy Rule (*Typog.*) Brass rule, the face of which is in the form of waves.

Wax (*Chem.*). A name given to many substances, of animal and vegetable origin, of very different chemical composition, but possessing some of the physical properties of beeswax. A true wax contains one or more of the following classes of compounds: (1) An ester composed of a higher fatty acid and a higher fatty alcohol; (2) An ester composed of a higher fatty acid and glycerine; (3) A free fatty acid. Of these (1) must be a constituent.

Wax.	*Ester* (1).	*Ester* (2).	*Fatty acid* (3).
Beeswax.	Myricyl palmitate (*See* PALMITIC ACID) Ceryl cerotate.	—	Cerotic acid
Chinese wax	Ceryl cerotate. (*See* CERYL ALCOHOL)	—	—
Japan wax	—	Glyceryl palmitate	Palmitic acid
Spermaceti	Cetyl palmitate	—	—

Paraffin wax is on the above definition not a wax at all; it is a mixture of the higher solid hydrocarbon of the paraffin series. *See also* BEESWAX: SPERMACETI.

Waxed Leather (*Leather Manufac.*) Leather finished flesh side outwards. The leather is coated with a size or waxing solution made of oil, lampblack, and gelatine. Sometimes small quantities of various waxes are used to give a good polished appearance.

Way Leave, Way Lease. Permission obtained from the owner for the carrying of a pipe, wire, etc., across any property.

Ways (*Eng.*) (1) Longitudinal guides for a table which supports and advances work in the direction of the operating tool. (2) The massive timbers along which a ship slides into the water when being launched.

Wealden Rocks (*Geol.*) The lowest division of the Cretaceous system, resting on the Jurassic Rocks. *See* STRATA, TABLE OF (Appendix).

Weather (*Meteorol.*) The atmospheric conditions that prevail at any particular moment or during a short period of time as shown by the meteorological elements. *See* METEOROLOGY.

Weather Boarding (*Carp. and Join.*) Feather-edged boards fixed horizontally, the thick edge of one board overlapping the thin edge of the next. Used on roofs and walls of wooden buildings.

Weathering (*Build.*) Forming a sloping surface on sills, etc., in order to throw off rain water.

—— (*Geol.*) The process of decomposition which occurs in the superficial layers of rocks where they are exposed to atmospheric influences.

Weather Lore (*Meteorol.*) Sayings relating to weather based on observations of weather sequences and noting the foreshadowed effects of certain atmospheric conditions on objects animate and inanimate.

Weather Maps (*Meteorol.*) Charts which show the prevailing atmospheric conditions at any particular moment of time.

Weather Moulding (*Architect.*) *See* HOOD MOULD.

Weaver's Warp *or* **Web** (*Textiles*) A warp containing a number of ends placed side by side and wound or coiled in laps on a beam ready for the loom.

Weaving. *See* LOOM, COTTON, LINEN, SILK, WOOL.

Weaving Plan (*Weaving*). A plan showing the working design on the least number of healds, shafts, and picks possible. From this the tappets are set, or dobby lattices are pegged, so as to produce the correct pattern in cloth. Other terms are: tappet plan, lifting plan, pegging plan, tie up.

Web (*Eng., Build., etc.*) The central vertical part between the flanges of a girder.

Web (*Paper Manufac.*) The term usually applied to the sheet of paper as it comes wet from the machine wire.

—— (*Weaving*). (1) The warp in a loom. (2) The whole piece cloth woven in the loom. (3) A piece of linen cloth of specific size.

Weber (*Elect.*) An old term for the AMPÈRE (*q.v.*)

Web Glass (*Textiles*). A glass used for counting the number of threads in a given space of the cloth to find the set or fineness. 37″, 38″, and 40″ are the glasses most commonly used in Ireland. These are respectively the 200th part of 37, 38, and 40 inches as the set of the cloth is so many 200 threads in 40″ in the red, or 38″ of brown cloth, or 37″ of white cloth, or something near to this. *See* SET.

Web Machine (*Print.*) A printing machine on which the sheets are carried forward to the impression cylinder by means of tapes.

Websterite (*Min.*) A hydrous sulphate of alumina, $Al_2SO_6 . 9H_2O$; occurs in earthy white masses in Kent, Sussex, and elsewhere, usually in the chalk "pipes."

Wedge Photometer (*Astron.*) *See* PHOTOMETER.

Wedgwood Ware. Josiah Wedgwood (1730—1795) commenced business on his own account in 1759. He took Thomas Bentley into partnership in 1768. His manufactory at Etruria, Staffordshire, was opened in 1769. The name of Wedgwood will ever remain associated with some of the finest keramic productions of the eighteenth century. The Jasper Cameo wares, the black basalt statuettes, and the models by Flaxman, as well as the classical forms, are of the greatest beauty.

Weft, Woof, or Shoot (*Textile Manufac.*) The yarn or thread added to the warp in weaving by means of the shuttle passing to and fro from selvedge to selvedge. Also termed "abb" in the West of England, and "filling" in America. It is usually spun softer than the warp yarn, being twisted less. "Cop" weft (*q.v.*) is generally twisted in the opposite direction to warp (*q.v.*)

Weft, Backing (*Textile Manufac.*) Special yarn, usually thicker in counts than that used for the face weft, and confined to the back of the cloth in weaving, for giving weight and substance.

Weft Fork (*Textile Manufac.*) A simple and ingenious contrivance for stopping a loom automatically should the weft in shuttle break or become exhausted.

Weighting (*Textile Manufac.*) The variable amount of tension required to be applied to beams or warp to keep the warp yarns in proper position on the loom: or in lace manufacture to obtain various effects. *See* LOOM.

Weights and Measures. The English standards of weights and measures are derived from certain arbitrary standards preserved by the Board of Trade. The chief of these are the YARD, which is legally defined as the distance between two marks on a standard metal bar, measured at 62° F., and the POUND, of which the standard is the mass of a certain piece of platinum. Duplicates of these standards, which have been accurately compared with the originals, are also preserved in various places.

I. ENGLISH MEASURES.

(1) *Length* (Linear Measure).

12 inches (*ins.*) = 1 foot (*ft.*)
3 feet = 1 yard (*yd.*)
5½ yards = 1 rod, pole, or perch.
40 poles (220 yards) = 1 furlong.
8 furlongs = 1760 yards = 1 mile.
1 geographical mile = 6082·66 feet.
1 nautical mile = 6080 feet.
3 miles = 1 league.

Surveyors use the following:

1 chain = 100 links = 22 yards.

Electricians use a unit termed a mil.

1 mil = ·001 inch.

Miners and sailors use the fathom = 6 feet (*approximately*).

(A cable = 100 fathoms, 10 cables = 1 geographical mile.)

(2) *Area* (Square Measure).

144 square inches = 1 square foot.
9 square feet = 1 square yard.
30¼ yards = 1 square rod, pole, or perch.
40 square rods = 1 rood.
640 acres (3,097,600 square yards) = 1 square mile.

Surveyors use:

484 square yards = 1 square chain.
10 square chains = 1 acre.

(3) *Volume* (Cubic Measure).

1728 cubic inches = 1 cubic foot.
27 cubic feet = 1 cubic yard.
4 gills = 1 pint.
2 pints = 1 quart.
4 quarts = 1 gallon = ·16057 cubic feet.
2 gallons = 1 peck.
4 pecks = 1 bushel.
8 bushels = 1 quarter.

A great number of other measures are used in various trades, *e.g.* various multiples of the gallon, which are employed by dealers in wine, spirits, etc.

(4) *Weight.*

AVOIRDUPOIS WEIGHT.

16 drams = 1 ounce (*oz.*) = 437·5 grains.
16 oz. = 1 pound (*lb.*) = 7000 grains.
28 lb. = 1 quarter.
4 qrs. = 1 hundredweight (*cwt.*) = 112 lb.
20 cwt. = 1 ton = 2240 lb.

TROY WEIGHT.

24 grains = 1 pennyweight (*dwt.*)
20 pennyweights = 1 ounce (*oz.*) = 480 grains.
12 ounces = 1 pound.

The ounce troy is legal (but not compulsory) for the sale of gold, silver, precious stones, etc.

APOTHECARIES WEIGHT.

20 grains = 1 scruple.
3 scruples = 1 dram.
8 drams = 1 ounce.

The grain, ounce, and pound in Apothecaries Weight are the same as in Troy Weight. This measure is legal (but not compulsory) for the sale of drugs.

(5) *Angular Measure.*

60 seconds (60″) = 1 minute (1′).
60 minutes (60′) = 1 degree (1°).
90 degrees (90°) = 1 right angle.

(6) *Measures of Time.*

60 seconds = 1 minute.
60 minutes = 1 hour.
24 hours = 1 day = 86,400 seconds.

II. METRIC SYSTEM. This is a decimal system of weights and measures, in which only multiples of 10 are employed. It is used by most continental countries and their colonies, and in most scientific work.

The standard of length is the METRE, which was intended to be one ten-millionth of the earth's quadrant; it is now defined by a standard bar termed the *Mètre des Archives*, preserved by the French Government.

The multiples and sub-multiples of any unit are denoted by the following prefixes:

$\frac{1}{1000}$ of a unit by the prefix MILLI-.
$\frac{1}{100}$ " " " CENTI-.
$\frac{1}{10}$ " " " DECI-.
10 units by the prefix DECA-.
100 " " " HECTO-.
1,000 " " " KILO-.
10,000 " " " MYRIA.

(1) *Length.*

10 millimetres (*mm.*) = 1 centimetre (*cm.*)
10 centimetres = 1 decimetre.
10 decimetres = 1 metre (*m.*)
10 metres = 1 decametre.
10 decametres = 1 hectometre.
10 hectometres = 1 kilometre.
The metre = 39·371 inches.

(2) *Area.*

100 sq. mm. = 1 sq. cm.
100 sq. cm. = 1 sq. decimetre.
100 sq. decimetres = 1 sq. metre.
100 sq. metres = 1 sq. decametre or 1 are.

In measuring land, the are and its multiples are employed. 1 hectare = 2·471 acres.

(3) *Volume.*

The cubic centimetre and its multiples are used; a special name, the LITRE, is given to the cubic decimetre (1000 c.c.) and multiples of this measure are used. A cubic metre is termed a STERE.

The litre = 1·76 English pints.

(4) *Weight.*

The unit is the gram, which was intended to be the mass of a cubic centimetre of water at its maximum density. In practice it is $\frac{1}{1000}$ of the *Kilogramme des Archives.* (*Cf.* Metre.) The usual multiples, etc., are used; a special name, the TONNE, is given to 1000 kilograms.

1 gram = 15·432 grains.
1 tonne = ·9842 ton.
1 pound = 453·593 grams.

5. *Angular Measure.*

A decimal division of the right angle was drawn up in the eighteenth century, but is not in practical use. It was as follows:

100 seconds = 1 minute.
100 minutes = 1 grade.
100 grades = 1 right angle.

Weirs (*Civil Eng.*) A weir is a barrier placed across a stream in order to raise its level. SOLID WEIRS are banks of masonry, stones, piling, etc., usually of a triangular cross section, or walls of masonry, which may be combined with concrete. DRAW DOOR WEIRS possess vertical sliding doors, which can be raised in times of flood. A good example is found in the weir at Richmond (Surrey), in which doors 12 ft. high are raised and lowered by cables from the footbridge above. MOVABLE WEIRS are more or less temporary barriers; there are various forms, of which some of the commonest are as follows: NEEDLE WEIRS consist of a row of timbers placed vertically (or nearly so) across the stream, the bases resting against a sill, the tops against a continuous bar crossing the river. They are chiefly found in France and the Low Countries. PANEL WEIRS are of somewhat similar type, but wooden panels are substituted for the narrow timbers. CURTAIN WEIRS have a rolling partition, somewhat like the rolling shutter used in shops, special forms of hinge being used in order to produce a watertight joint. DRUM WEIRS have a shutter or leaf, hinged along one end and rotated in a DRUM or quadrant shaped cavity.

Weld (*Eng., etc.*) Welding is the process of forming a homogeneous joint between two pieces of iron (or mild steel) by heating them to a high temperature, termed a WELDING HEAT, rapidly cleaning off slag and other surface impurities, and pressing and hammering them together. A flux, such as clean sand or borax, is commonly used to facilitate the removal of oxide, etc., from the surface.

Welding Heat (*Eng., etc.*) A temperature of 2500° to 2700° F. in the case of wrought iron; steel welds at a lower temperature.

Weldon Process (*Chem.*) A process employed to reconvert the manganese chloride obtained in the preparation of chlorine from manganese dioxide and hydrochloric acid, into manganese dioxide again. The liquor from the chlorine still is allowed to settle; it is then neutralised with chalk, which also precipitates iron (present in native manganese dioxide); the clear liquor from this process is mixed with milk of lime heated to 55°, and air blown through it. This oxidises the manganese hydroxide precipitated by the milk of lime to manganese dioxide, which unites with some of the calcium hydroxide to form calcium manganite: the latter settles on standing—the deposit, known as Weldon mud, is used to generate chlorine $CaMnO_3 + 6HCl = CaCl_2 + MnCl_2 + 3H_2O + Cl_2$. Much less chlorine is made in this way now than formerly, so that this process is not so much used.

Wells. Wells are classified as DEEP or SHALLOW according to whether they do or do not pass through an impermeable stratum of sufficient thickness to cut off the surface water. The division is thus independent of the actual depth of the well. *See* ARTESIAN WELLS, SHALLOW WELLS, DEEP WELL WATER, *and under* SANITATION.

Welsbach Incandescent Mantle (*Chem.*) A mantle (*q.v.*) composed chiefly of thorium oxide, with 1 per cent. of cerium oxide. *See also under* FLAME, *p.* 224.

Welsh Harp (*Music*). A harp having three rows of strings, the two outside rows being in unison, and the inner so tuned as to complete the chromatic scale. It has the strings on the right side, and is held on the left shoulder. The treble is played with the left hand and the bass with the right. *See also* HARP, *p.* 429.

Welt (*Eng.*) The strip of iron laid over a butt joint (*q.v.*)

Welt Joint (*Plumb.*) A joint formed by folding the edges of sheet lead, zinc, etc., one over the other.

Wenlock Series (*Geol.*) The middle division of the SILURIAN ROCKS, equivalent to the SALOPIAN (*q.v.*)

Wernerite (*Min.*) A synonym for SCAPOLITE (*q.v.*)

Werner's Theory (*Chem.*) Is an extension of the theory of valency so as to explain the formation, constitution, and transformations of those complex compounds whose formation, constitution, and trans-

formations appear to be otherwise incapable of explanation. For instance, on none of the ordinary assumptions as to the valency of any of the elements of the following compounds can their existence be interpreted:

$$MgCl_2 6H_2O,\ K_3Co(NO_2)_6,\ Cr(NH_3)_6Cl_3,\ PtCl_6K_2$$

Werner assumes that those atoms which are able to form what may be called the central atoms of these complex compounds possess two kinds of valency—a Principal and a Subsidiary. The Principal Valency is the ordinary valency exhibited by the atoms in their simplest and most stable compounds, or it is the valency exhibited by the element or group when it exists in solution as an ion. The Subsidiary Valency is a residual valency exhibited by compounds formed from elements united by Principal Valency, and as such compounds can never be ions, or act as equivalent to ions, subsidiary valency may be defined as a valency which unites to each other compounds which can neither act as independent monovalent ions nor be equivalent to them. Compounds in whose formation only principal valencies are satisfied are called compounds of the first order; compounds formed by the union of compounds of the first order are called compounds of higher order. These definitions are illustrated by the following examples: (1) Sulphur trioxide unites with water to form sulphuric acid. This union is assumed to occur in the first place by means of the subsidiary valency of the sulphur in the trioxide and the oxygen in the water. This subsidiary valency is always shown by a dotted line. The union is expressed thus:

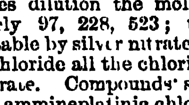
$$\begin{array}{c}O\\OS\\O\end{array} + OH_2 = \begin{array}{c}O\\OS\\O\end{array}\ldots OH_2$$

(2) A quite analogous case is the union of gold trichloride with hydrochloric acid to form chloroauric acid:

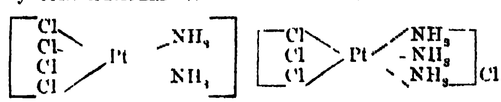
$$\begin{array}{c}Cl\\ClAu\\Cl\end{array} + ClH = \begin{array}{c}Cl\\ClAu\\Cl\end{array}\ldots ClH$$

(3) Platinic chloride unites with two molecules of hydrochloric acid and with two molecules of ammonia:

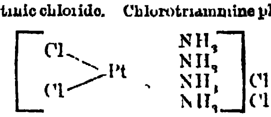
In examples (2) and (3) the subsidiary valencies of the compounds of the first order reside on the atoms joined by the dotted lines. It may be observed that on the ordinary theory of valency gold chloride, platinic chloride, hydrochloric acid, are all saturated compounds, yet we find them uniting to form quite stable compounds, and the same thing is observed in a very large number of cases, so that some such assumption as that of subsidiary valency appears to be fully justified. The principal valencies and the subsidiary valencies in compounds of higher order are not independent of each other. This is shown by the frequency with which compounds of higher order are formed from compounds of the first order which contain common elements, by the fact that many higher oxides in the free state are very unstable, while their salts are quite stable, by the fact that several higher chlorides, for instance, lead tetrachloride, are unstable, while their double chlorides are stable, *e.g.* $(NH_4)_2PbCl_6$, and finally by the fact that the subsidiary valency depends for its value on the nature of the elements or groups that satisfy the principal valencies, *e.g.* cadmium bromide unites with six molecules of pyridine, while the nitrate only takes up two. The number of subsidiary valencies of compounds of the first order is limited. This number is, of course, only capable of being deduced by considering all the compounds of higher order that can be formed from the compound of the first order under consideration. It probably never exceeds six; in platinic chloride, cobaltic salts, in the iron of ferricyanides, and in the iron of ferrocyanides it is two, three, three, and four respectively. The total number of atoms united directly to the central atom in compounds of higher order, whether they are united by a principal valency or a subsidiary valency, is called the co-ordination number. The maximum co-ordination number in the majority of cases is six; but it varies with the nature of the central element—in the cases of carbon and nitrogen it is four. Now consider the compound diammineplatinic chloride



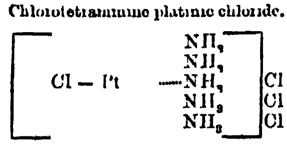
: it is unacted on by boiling sulphuric acid; silver nitrate does not give a precipitate of silver chloride when added to its solution; its solution shows no electrical conductivity. These facts show that the chlorine is quite incapable of behaving as the chlorine in an ordinary chloride—it is not ionisable. By taking up ammonia it can yield compounds containing one, two, and four more molecules of ammonia. These new compounds show electrical conductivity; at 1,000 litres dilution the molecular conductivity is respectively 97, 228, 523; the chlorine becomes precipitatable by silver nitrate, till in the hexammineplatinic chloride all the chlorine is precipitatable by silver nitrate. Compounds such as the tri-, tetra-, and hexa-ammineplatinic chlorides are called Interposition Compounds, because the entering ammonia molecules have displaced chlorine atoms in such a way that the ammonia molecules are now interposed between the chlorine atoms and the platinum atom, and the chlorine, as the ammonia has interposed, has become ionisable. These relationships are indicated by constitutional formulæ as follows:



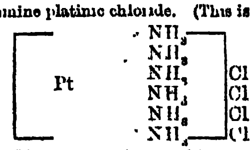
Diammine platinic chloride. Chlorotriammine platinic chloride.



Chlorotetrammine platinic chloride.



Chloropentammine platinic chloride. (This is yet unknown.)



Hexammine platinic chloride.

It is seen that in each compound there are six

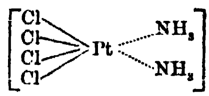
co-ordinated atoms or groups: these groups are assumed to occupy the space around the platinum atom, while the other atoms—those outside the brackets—are regarded as being in an outer sphere, but still acted on by the central platinum atom. It should be noticed that the maximum number of atoms that can occur in the outer sphere equals the maximum principal valency of the central atom. Also, it is the atoms of the outer sphere only that are ionisable. The platinum atom may be assumed to be at the centre of a regular octahedron and the co-ordinated groups at the angular points: the atoms outside the brackets in the above formulæ are assumed to be in an outer sphere in a way not yet specified. If the spacial arrangement just described be true, cases of isomerism should occur. For instance:

$$[Cl_2Pt(NH_3)_4]Br_2$$
(Dichlorotetrammine platibromide)

should be isomeric with

$$[Br_2Pt(NH_3)_4]Cl_2$$
(Dibromotetrammine platichloride)

and this is found to be the case. Werner calls this ionisation isomerism. Many examples are known. Again, two compounds of the formula



should exist, namely:

I 
These have long been known, and I. is the diammine platinic chloride and II. the semidiammine platinic

II 
chloride. This kind of isomerism is called by Werner Space Isomerism. Many examples are known.

In compounds of the first order an element does not always act with its maximum principal valency; for instance, we have stannous chloride, $SnCl_2$, and stannic chloride, $SnCl_4$. So in compounds of higher order, a central atom does not always act with its maximum co-ordination number—that is, a series of co-ordinatively unsaturated compounds should exist. Several such series are known. These compounds also form interposition compounds; an example is:

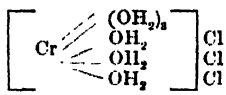
$[Pt(NH_3)_4]Cl_2$	$\left[Pt{(NH_3)_3 \atop Cl}\right]Cl$	$\left[Pt{(NH_3)_2 \atop Cl_2}\right]$
Tetrammine platochloride. 260.	Chlorotriammine platochloride. 116.	Dichlorodiammine platochloride. 0

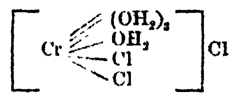
$\left[Pt{NH_3 \atop Cl_3}\right]K$	$[PtCl_4]K_2$
Potassium amminoplatochloride. 107.	Potassium platochloride. 267.

The numbers give the molecular conductivity at 1,000 litres dilution. These compounds can be represented graphically, as shown above, by abolishing the vertical axis; also isomerism should occur in the case of the dichlorodiammineplato chloride, and this is the case. To give even a list of the so-called "double salts" to which this theory has been applied, and applied with astonishing success, would far exceed the limits of this article; but a few examples are added: the complex cobalt-ammonium salts, the corresponding chromium salts, the complex double salts of vanadium, molybdenum, tungsten, the cobaltinitrites, etc. Many salts crystallise with six molecules of water of crystallisation; examples are:

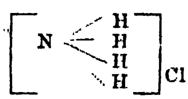
$$CaCl_2 6H_2O : AlCl_3 6H_2O : CoCl_2 6H_2O : Zn(NO_3)_2 6H_2O : CrCl_3 6H_2O$$

These are regarded as follows, $[Ca(OH_2)_6]Cl_2$—that is, the metal in the central element and the six molecules of water are co-ordinated with it through the subsidiary valency of the oxygen. A remarkable consequence of this is that on Werner's view the ions in these salts will be $\overset{2+}{[Ca(OH_2)_6]}$ and $2\,\overline{Cl}$. Another interesting point is furnished by the blue hexahydrate of chromium chloride—this loses two molecules of water readily and forms the green tetrahydrate. Now, all the chlorine of the hexahydrate is precipitated by silver nitrate, while only one-third of the chlorine is precipitated in the case of the tetrahydrate. These results are easily expressed by formulæ:

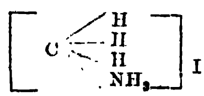




The theory offers a very natural account of the ammonium compounds. The co-ordination number for nitrogen is four, so we have—



which accounts, without any forcing, for the fact that ammonium salts behave like salts of the alkali metals, while the pentavalent nitrogen theory does not. The formation of the organic ammonium compounds is explained on the same plan as methylamine hydriodide:



A large number of acids containing four oxygen atoms is known. As typical of these may be mentioned:

$$[SiO_4]H_4, [PO_4]H_3, [SO_4]H_2, [ClO_4]H.$$

All these are regarded as co-ordinated compounds, and it will be noticed that the valency of the co-ordinated group diminishes in passing from Group IV. to Group VII. of the Periodic System. Now, there are oxides of Group VIII. of the Periodic System—*e.g.* RuO_4 and OsO_4—which are richer in oxygen than any of the oxides from which the above acids are derived, and it is remarkable that these oxides no longer unite with water to form acids. Thus in the majority of cases (a few exceptions are

known) four is the maximum co-ordination number for oxygen. In these cases also interposition compounds can exist; for example:

$$\left.\begin{array}{ccc} O & & O \\ & P & \\ O & & O \end{array}\right| H_3 \text{ Phosphoric acid (Tribasic);} \quad \left[\begin{array}{ccc} O & & O \\ & S & \\ O & & O \end{array}\right] H_2 \text{ Sulphuric acid (Dibasic);}$$

$$\left.\begin{array}{ccc} O & & O \\ & P & \\ O & & H \end{array}\right| H_2 \text{ Phosphorous acid (Dibasic);} \quad \begin{array}{ccc} O & & O \\ & S & \\ O & & H \end{array} H \text{ Suphurous acid (Dibasic);}$$

$$\begin{array}{ccc} O & & H \\ & P & \\ O & & H \end{array} H \text{ Hypophosphorous acid (Monobasic).}$$

That sulphurous acid is dibasic is to be explained on the supposition that sulphurous acid can react in the tautomeric forms—

$$\left[\begin{array}{ccc} O & & O \\ & S & \\ O & & H \end{array}\right] H \text{ and } \left[\begin{array}{ccc} O & & O \\ & S & \\ O & & . \end{array}\right] H_2$$

Cases are known in which tautomerism does in fact occur. The case of the heptahydrated sulphates (vitriols) is met by assuming that some molecules of water are co-ordinated with the metallic element, while some are co-ordinated with the acid residue; this case is apparently not yet worked out. Again, in salts like the alums, which contain a very large amount of water of crystallisation, it is necessary to assume the existence of double water molecules, which are co-ordinated like single atoms or molecules—an assumption which Werner justifies by pointing to the known molecular association of water in the liquid state. The cases of the vitriols and alums may be regarded therefore as either insufficiently examined as yet or as arguments against Werner's theory: but in view of the enormous number of compounds which this theory has rendered intelligible and capable of classification, the former appears the more probable assumption.

Westinghouse Brake (*Eng.*) *See* RAILWAYS, *p.* 599.

Wet and Dry Bulb Hygrometer (*Phys. and Meteorol.*) *See* HYGROMETERS.

Wet End (*Paper Manufac.*) The term applied to the portion of the machine where the wet pulp is made into a sheet of paper.

Wet Press Machine. *See* WOOD PULP.

Wet Puddling (*Met.*) *See* PIG BOILING.

Wet Steam (*Eng.*) Steam in which partial condensation has occurred, or which has been mixed with water spray in the boiler.

Wetting Board (*Print.*) A board placed between the reams of paper in the process of wetting down.

Wetting Down (*Print.*) Ordinary printing papers are occasionally wetted down before printing. The ream is quired and placed on the left of the wetting trough. A quire is then taken, and one end dipped in the water and the whole drawn through. A dry quire is placed on top of the wet one, and so on alternately. Boards are placed between and on top of the reams. Weights are put on top of the pile, and the paper allowed to soak for several hours. The sheets are then turned, and afterwards placed in a screw press and fastened down. The object of the process is to facilitate deposition of the ink evenly upon the paper.

w.f. (*Print.*) The abbreviation generally used for Wrong Fount (*q.v.*)

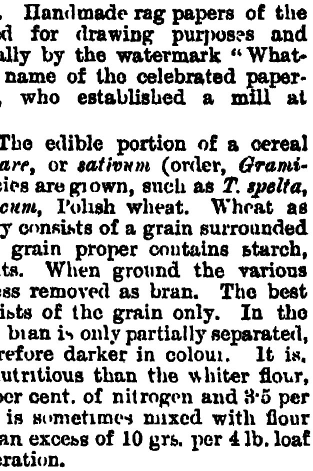
Whale Oil. The two kinds of whale oil of commerce are known as TRAIN OIL obtained from the Right Whale and certain other species, and SPERM OIL from the Sperm Whale. The latter is the most valuable lubricant for machinery known. *See* OILS *and* LUBRICANTS.

Wharfedale Machine (*Print.*) *See* TYPOGRAPHY.

Whatman Papers. Handmade rag papers of the highest quality used for drawing purposes and ledgers, known specially by the watermark "Whatman," this being the name of the celebrated paper-maker J. Whatman, who established a mill at Maidstone in 1760.

Wheat (*Foods*). The edible portion of a cereal grass, *Triticum vulgare*, or *sativum* (order, *Gramineæ*.) Many subspecies are grown, such as *T. spelta*, the Spelt; *T. polonicum*, Polish wheat. Wheat as grown in this country consists of a grain surrounded by four coats. The grain proper contains starch, proteid, fat, and salts. When ground the various coats are more or less removed as bran. The best quality of flour consists of the grain only. In the second-rate flours the bran is only partially separated, and the flour is therefore darker in colour. It is, nevertheless, more nutritious than the whiter flour, as bran contains 15 per cent. of nitrogen and 3·5 per cent. of fat. Alum is sometimes mixed with flour to render it whiter; an excess of 10 grs. per 4 lb. loaf is regarded as adulteration.

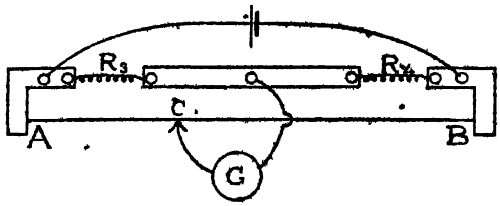
Wheatstone's Bridge (*Elect.*) An arrangement in which two resistances whose ratio is known are employed for the comparison of two other resistances, one of which is variable. Let R_1 and R_2 be two resistances whose ratio is known, or RATIO ARMS, R_3 a resistance which can be varied, R_4 an unknown resistance. These are connected with each other and with a battery B, and galvanometer G, as shown. R_3 is now adjusted till no current flows through G; when this is the case, it can easily be shown that—



$$\frac{R_1}{R_2} = \frac{R_3}{R_4} \text{ or } R_4 = R_3 \times \frac{R_2}{R_1}.$$

Thus if R_3 and the ratio $\frac{R_2}{R_1}$ be known, R_4 is determined. When this relation is satisfied, the two conductors which contain the battery and the galvanometer respectively are said to be CONJUGATE CONDUCTORS; their relation is such that an electromotive force in one of them does not affect any current which may be flowing in the other. Hence any alteration in the E.M.F. of the battery has no effect on the accuracy of the measurements made with the bridge. The most typical forms of bridge are the SLIDE WIRE BRIDGE and the POST OFFICE

Box. In the former, the ratio arms are formed by a straight bare wire of German silver, or other suitable alloy, AB. This is mounted on a base board and



connected with the resistances R_3 and R_4 by heavy copper or brass conductors. The battery is connected as shown: one end of the wire from the galvanometer G goes to the conductor connecting R_3 and R_4, the other end, C, terminates in a sliding contact which can be moved along AB till a "balance" is obtained, *i.e.* until no current flows through the galvanometer. The lengths AC and BC are read off on a scale and the ratio of their lengths gives the ratio of the resistances of the portions AC and BC, *i.e.* the ratio of R_1 to R_2. As AB is commonly made 1 metre long, this form of bridge is often termed the METRE BRIDGE; it is also in a modified form known as the B A. BRIDGE (British Association).

In the Post Office Box, the ratio arms are usually formed by two sets of resistance coils, each set containing 10, 100, and 1000 ohms, either of which can be included in the circuit by means of plugs. The arm R_3 is formed by a set of coils which can be used singly or in combination so as to give resistances increasing by single ohms from 1 to 10,000 or more. The top of the box carries the plugs by which contacts are made, binding screws for connecting the battery, etc., and keys by which the battery and galvanometer circuits are made and broken. The method of use is based upon the same general principles as the foregoing. A DIAL BRIDGE is one in which the resistances are varied by moving a radial arm over a series of metal studs connected with the coils, thus avoiding the use of loose plugs.

Wheel Base (*Eng., etc*) The distance between the centres of the fore and hind wheels of a cycle, motor car, locomotive, etc.

Wheel Cutting (*Eng.*) The process of forming the teeth of wheels by a rotating cutter of the proper cross-section.

Wheel Moulding (*Foundry*). Forming the mould for casting toothed wheels Instead of using a complete pattern, a segment of the wheel is employed in many cases, in conjunction with a moulding machine (*q v.*)

Wheel Ore (*Min.*) A synonym for BOURNONITE (*q.v*)

Wheel Swarf (*Eng*, *etc*) The material removed from a grindstone and from the object being ground; it forms the muddy deposit in the trough under the stone and is sometimes utilised in metallurgical operations.

Wheel Teeth (*Eng.*) Wheel teeth must be so shaped that smooth sliding contact occurs in every position without variations in the velocity ratio of the two wheels; and further, the shape must be such as to give the necessary strength and ease of construction. In practice the curves adopted are nearly always portions of cycloidal curves (*see* EPICYCLOID *and* HYPOCYCLOID). The PITCH CIRCLES of two toothed wheels are two imaginary circles of such diameter that they would roll together with the same relative angular velocities as the actual toothed wheels. The teeth lie partly inside the circle and partly outside; the portion of a tooth within the pitch circle is called the ROOT, and the portion outside is called the POINT, or ADDENDUM. The profile of the teeth is the path traced out by a point on an imaginary circle, termed a DESCRIBING CIRCLE, which rolls on the pitch circles so as to be in contact with both, *i.e.* which touches both the pitch circles at their point of contact. If the same describing circle be used for any number of wheels they will all work with one another correctly, whatever their diameters. The diameter of the pitch circle must not, however, be less than half that of the smallest wheel in the set In this case the flanks (or profiles of the roots) of the smallest wheel are radial lines.

Another form sometimes given to teeth is the INVOLUTE, the curve generated by a point in a string which is being unwound from a cylindrical surface and kept tight throughout the operation. The whole profile of an involute tooth is one continuous curve; and wheels with such teeth possess the peculiar property that the centres of two wheels gearing with one another may be brought nearer together or farther apart without affecting the uniformity of their action or their velocity ratio.

Wheel Window (*Architect.*) *See* ROSE WINDOW.

Whetstone. A piece of fine grained hard stone, *e g.* slate, or an artificial stone of the same character, suitably fixed, used for sharpening cutlery and tools.

Whiffle *or* **Whipple Trees.** The horizontal bars by which horses are yoked to a vehicle.

Whim (*Mining*) A primitive form of winding machine, consisting of a drum mounted on a vertical axis, worked by a horse, or even by manual labour.

Whin *or* **Whinstone** (*Geol.*) A term often used locally by miners and quarrymen for any hard rock, *e g.* Basalt. The WHIN SILL is a great eruptive sheet cutting across the Carboniferous Rocks of the Pennines, and forming many striking physical features, such as crags and waterfalls

Whipping (*Bind.*) This term signifies the same process as OVERCASTING (*q.v.*), except that the stitches are longer.

Whipple-Murphy Girder (*Eng*) A form of built-up girder having its bars arranged in the form of the letter N.

Whip Threads (*Textile Manufac*) Threads in gauze weaving which whip or twist round adjacent threads.

Whirlwind (*Meteorol.*) Circular air movements set up by the meeting of two air currents differing in direction.

Whisky. A spirit originally distilled from malted grain, containing about 50 per cent of alcohol.

White Arsenic (*Chem*) *See* ARSENIC COMPOUNDS.

—— (*Min*) Occurs occasionally native as an incrustation on minerals containing arsenic.

White Cast Iron (*Chem.*) *See* IRON.

Whitefriars Machine. (*Print.*) A rotary machine designed for the printing of newspapers from single sheets or reels. It consists of four cylinders arranged round a crescent-shaped frame, the inking arrangements being placed at each end.

White Heat. The temperature at which a body emits white light. The "white heat" of the smith is the temperature to which a large piece of iron is heated before removal from the fire. It is between 1300° and 1500° C.

White Lead (*Chem.*) See LEAD COMPOUNDS.

White Lead Ore (*Min.*) A synonym for CERUSSITE (*q.v.*)

White Light (*Phys.*) Light in which all the colours of the spectrum are present in their proper proportion. See SPECTRUM.

White Line (*Print.*) A line of quadrats forming (*a*) a blank space in the text equal to one line, (*b*) the foot line of a page.

White Metal. Another name for BABBITT'S METAL (*q.v.*) See also COPPER and TIN.

White Nickel (*Min.*) A synonym for CLOANTHITE (*q.v.*)

White Out (*Typog.*) To space out lines or matter in order to give it a more open appearance.

White Paper (*Print.*) A technical term for all unprinted paper white or coloured.

White Precipitate (*Chem.*) See MERCURY COMPOUNDS.

White Soap. Soap manufactured by boiling fat with caustic lye, removing the imperfect and unformed soap by means of common salt, reboiling after the removal of the waste lye, and finally cooling. Sometimes an additional boiling is given, and the soap thus made may be used as the base or stock of toilet soaps (*q.v.*) Curd soap, according to the British Pharmacopœia, must be made from soda and a purified animal fat consisting principally of stearin. See SOAP MANUFACTURE.

White Squalls (*Meteorol.*) These are fair weather squalls, and occur when conditions are suitable for spout formation but sufficient moisture is wanting to fill up the central vortex.

White Vitriol. A trade name for sulphate of zinc. See ZINC COMPOUNDS.

—— (*Min.*) A synonym for GOSLARITE (*q.v.*)

Whitewash (*Build.*) Chalk lime mixed with water. A little tallow is added to prevent it being rubbed off when dry.

White Wood. See WOODS.

Whiting. Pure white chalk which has been ground and washed.

Whitworth Thread (*Eng.*) See SCREW THREADS.

Whole Bound (*Bind.*) See FULL BOUND.

Whole Note (*Music*) The semibreve (*q.v.*)

Whole Plate (*Photo.*) A plate measuring 8½ by 6½ inches.

Whorl (*Botany*) An arrangement of the parts of a plant in which a number spring from the same point, and are arranged regularly round the stem.

Wick. See CANDLES.

Wicket. A small door or gate used as a subsidiary entrance in a large opening, and sometimes forming part of a larger door.

Wickets (*Chem. Eng.*) Gratings of lead, used in the manufacture of WHITE LEAD. See LEAD COMPOUNDS.

Wide Gauge (*Railways*). The BROAD GAUGE (*q.v.*)

Wide Spacing (*Typog.*) So termed when two thick spaces or more are placed between the words, as in this definition.

Wilhelmite (*Min.*) A silicate of zinc, hexagonal, yellow to brown. Found in Belgium and the United States.

Willow. See WOODS.

Willowing Machine (*Paper Manufac.*) The apparatus used for removing dust from esparto and other fibres.

Willow Leaves (*Astron.*) The name given to the visible structure in the penumbra of sun-spots.

Wimshurst Machine (*Elect.*) The best form of electrical influence machine. The typical form consists of two discs of glass, each carrying a number of sectors of tinfoil, and mounted so that they are rotated in opposite directions by turning a single handle. Each disc is touched by two uninsulated brushes, carried by the "neutralising rods." If any one sector receive a charge it induces charges of the opposite sign on sectors which are moving past it in the opposite direction; the result is the accumulation of continually increasing charges of positive and negative electricity at opposite edges of the discs, and these charges are collected by conductors suitably placed for the purpose. Large machines are also made with four, six, or more plates.

Winch (*Eng.*) Hauling or hoisting mechanism, consisting of a barrel round which a rope or chain is wound, and either provided with a handle and the necessary gearing for hand driving, or connected with a steam engine, electric, or other motor for power driving.

Wind (*Meteorol.*) Air in motion is called wind. Unequal heating gives rise to air motion or air currents, the passage of which gives the phenomenon of wind.

Wind Direction (*Meteorol.*) The direction from which the wind blows. It is indicated by means of a vane.

Winding (*Carp., etc.*) The surface of a piece of work is said to be "in winding" or to "wind," if it gradually twists.

—— (*Elect. Eng.*) The conductors of a dynamo, coil, electro-magnet, transformer, etc., which carry the electric current.

—— (*Textiles*) A convenient method of transferring the yarn from hank, cop, or bobbin, one thread at a time, for a considerable length, on to a bobbin or tube, *i.e.* cop winding, drum winding, pirn winding.

—— and **Winding Engine** (*Mining*) See MINING, *p.* 405.

Winding Sticks or **Strips** (*Carp. and Join., etc.*) Two pieces of wood with parallel edges used by joiners to show whether wood is winding. The strips are placed on edge on the wood to be tested, and the eye placed on a level with their upper edges, when any want of parallelism due to twisting or winding of the wood is at once seen.

Winding-up Tackle (*Lace Manufac.*) Worm and wheel gearing connected to the work roller, one of the factors determining the quality of the lace; analogous to the "taking off" motion in the loom.

Wind Instruments (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 431.

Windlass. A simple form of hand winch without gearing. *See* WINCH.

Windmill. A modern windmill consists of a set of radial vanes set at an angle capable of adjustment, and forming an almost complete disc, instead of having four or six vanes, as in the old form, which is still a familiar object in many districts. Owing to the uncertain and intermittent action of the wind, this form of motor is now little used, except for pumping water for drainage of land, irrigation, or filling tanks for small water supplies, where an occasional interruption in the flow is of no importance.

Window Board (*Build.*) The nosing board fixed to the sill inside a room.

Wind Pressure (*Eng., Build., etc.*) In large modern structures a wind pressure of 56 lb. per square foot is allowed for in calculating the strength of the members. It is very unlikely that the actual pressure ever exceeds 40 lb. The former limit was fixed by the Board of Trade after the Tay Bridge disaster in 1879.

—— (*Meteorol.*) The pressure or force exerted by the wind. Measured by the pressure it exerts on a flat surface placed perpendicular to its direction of motion.

Wind Trunk (*Music*). The tube which conveys the wind from the bellows to the wind chest.

Wind Velocity (*Meteorol.*) The rate of movement of wind. Measured by an anemometer (*q.v.*)

Wines. Light or natural wines contain from 6 to 13 per cent. of alcohol; strong or fortified wines, such as port and sherry, contain from 12 to 22 per cent. Besides alcohol, wines contain various aromatic ethers, which give the characteristic flavour or bouquet, sugar, acids, and salts.

Winged Globe (*Architect.*) One of the symbolical ornaments used by the Egyptians; a globe with outstretched wings. A scarab (sacred beetle), vulture, or a representation of the goddess Isis is frequently used instead of the globe.

Wing Nut (*Eng., etc.*) A nut provided with "wings" or projections, by means of which it may be turned by the thumb and fingers.

Wing Valve (*Eng.*) A valve provided with projections to guide it into its proper position.

Winning (*Mining*). A miners' term for the process of obtaining coal from the seam. *See* MINING.

Wincey (*Textile Manufac.*) A fabric with a rough, hard handle, formerly used for dresses.

Winter Solstice (*Astron.*) *See* SOLSTICES.

Wipe (*Print.*) A term used when the rollers leave an excess of ink on the edges of the forme.

Wiped Joints (*Plumb.*) A method of joining lead pipes. The upper end of the lower pipe is opened out about ¼ inch, and the lower end of the upper pipe is rasped so as to fit into the opened-out end. The ends of the pipes are then shaved so as to allow the solder to adhere to them. The pipes are next soiled above and below the soldering line with a mixture of lampblack and size, and the upper pipe is fixed into the lower with a collar round the bottom of the joint to catch the solder. The heated solder is then poured over the shaved ends of the pipes and worked into shape, the final process being the "wiping" of the joint with a hot moleskin cloth.

Wiper (*Weaving*). Another term for an eccentric or tappet. *See* TAPPET *and* LOOM.

Wire. Wire may be made of any metal possessing sufficient ductility to allow of drawing. Iron, steel, copper, and brass wire are the most common in the arts; the precious metals are also made into wire for decorative and other special purposes.

—— (*Textiles*). Used in velvet weaving to form the pile. Made of brass, flattened at the sides and having a groove through its entire length on the upper surface. It is placed in the shed under the pile warp, transversely, and is cut out as necessary by a sharp instrument called a truvat. The length of pile is regulated by the height and size of the wire. Wires for Terry (*q.v.*) weaving are quite round and made of steel.

Wire Brush. A brush made either entirely or partly of wire. Wire brushes are used for various purposes, *e.g.* by gilders for spreading gilt, for cleaning castings, etc.

Wire Card. *See* CARD WIRE.

Wire Cloth (*Paper Manufac.*) An endless cloth made of very fine wire, upon which pulp is formed into a sheet of paper.

Wire Drawing (*Eng., etc.*) (1) The production of wire by drawing a rod of metal through a hole in a steel plate of slightly smaller diameter than the rod; the process is repeated with successively smaller holes until wire of the requisite fineness has been obtained. (2) The reduction of the pressure of steam when it is caused to flow through narrow passages.

Wire Edge. The thin burr thrown up on the edge of a tool during grinding or sharpening on a stone.

Wire Gauge (*Eng.*) (1) A tool used for testing the diameter of wire or the thickness of metal plate. (2) A set of standard diameters to which wire, etc., is made, each designated by a special number. The BIRMINGHAM WIRE GAUGE (B.W.G.) is the one most commonly used, but others are also employed, *e.g.* the AMERICAN, *or* BROWN AND SHARPE, GAUGE. The numbers and diameters in inches of some of the principal sizes are as follows:

Number of Wire.	Diameter on Birmingham Wire Gauge.	Diameter on American Wire Gauge.
0	·340	·325
1	·3	·289
2	·284	·257
4	·238	·204
6	·203	·162
8	·165	·128
10	·134	·102
12	·109	·08
14	·083	·064
16	·065	·0508
18	·049	·0403
20	·035	·03196
25	·02	·0179
30	·012	·01
35	·005	·0056

Wire Micrometer (*Astron.*) *See* MICROMETER.

Wire Rope (*Eng.*) Rope formed by twisting fine wires of iron or steel, a hempen core being usually employed.

Witch Hazel (*Botany*). The dried bark and leaves of *Hamamelis virginica* (order, *Hamamelidaceæ*) are used in the preparation of a valuable astringent drug.

Witherite (*Min.*) Barium carbonate, $BaCO_3$; rhombic; in compound crystals; white to grey. Used as a source of barium compounds; also in sugar refining, porcelain and plate glass manufacture, and as a ratbane. In many localities in the Alston Moor District, in Central Europe, etc.

Withes (*Build.*) The partitions between the flues in a chimney stack.

Witness (*Bind.*) In the case of a book that is not to be "cut down" the edges are merely trimmed so as to make them straight and true. Some of the leaves still retain their rough edges, which are "witness" of the proper treatment.

Woad. A blue dye obtained from the pounded leaves of *Isatis tinctoria* (order, *Cruciferæ*). It is now replaced by indigo. *See* DYES AND DYEING.

Woad Vat. *See* DYES AND DYEING.

Wohltemperirte Klavier, Das (*Music*). The Well-Tempered Clavichord, the name given to "The 48 Preludes and Fugues" by J. S. Bach, who wrote them to show that by the new Equal Temperament tuning every key from C to B, both major and minor, was available.

Wolfram (*Chem.*) *See* TUNGSTEN.

—— (*Min.*) A tungstate of iron and manganese, the amounts of the two bases being variable. Monosymmetric, with a perfect cleavage; commonly found massive. Found in Cornwall, Cumberland, and in many other localities in Europe and America. It is used in the hardening of steel, for the fire-proofing of textile fabrics (as sodium tungstate), as a mordant, and in hardening plaster of Paris.

Wolframine (*Min.*) *See* TUNGSTIC OCHRE.

Wolf Rayet Stars (*Astron.*) A peculiar class of stars which have bright lines in their spectra.

Wolf, The (*Music*). A harsh, howling effect in certain intervals on keyed instruments tuned to the unequal temperament. This system was discarded in favour of the equal temperament in England about 1830 on the pianoforte, and about 25 years later on the organ.

Wollastonite (*Min.*) Also termed TABULAR SPAR. A metasilicate of lime, $CaOSiO_2$. Monosymmetric, but usually found massive. Colour white to reddish brown, translucent. Occurs in granite and certain other rocks.

Wood Block. A block of wood prepared for engraving. *See* ENGRAVING, *p.* 202, *and* WOODCUT.

Wood Carving. *See* CARVING.

Woodcut. An engraved wood block bearing a picture or design and made type high for use in a printing press. A print from such a block.

Wood Engraving. *See* ENGRAVING.

Wood Furniture (*Typog.*) Material used for dressing or imposing a forme. Of various thicknesses, and designated narrow, broad, double narrow, and double broad. *See* FURNITURE.

Wood Letter (*Typog.*) Large types cut in wood for use in posters for advertising, etc.

Wood Oil (*Botany*). *See* GURJUM BALSAM.

Wood Opal (*Min.*) Wood of which the tissues have been replaced by silica in the hydrous form Opal.

Wood Paving (*Civil Eng.*) This consists of a foundation or "formation" of concrete, carefully levelled; on this are laid the blocks, which are usually 9 in. long, 6 in. deep, and 3 in. wide. The blocks are laid with the fibres vertical, and the rows are at right angles to the main direction of the traffic. The joints between the blocks are filled with cement grout (thin, fluid cement) or with melted pitch; or both may be employed. The usual materials are certain of the Australian hard woods, *e.g.* blue gum, red gum, Jarrah, etc.

Wood Pulp. The use of wood pulp as a raw material suitable for the manufacture of paper dates from the year 1866. Attempts had been made previously to introduce wood for the purpose, but without material success. In 1801 Matthias Koops printed a book, the paper of which consisted almost entirely of wood pulp, though the method of manufacture was very crude. The industry received an impetus from the efforts of Voelter, who obtained patents in 1860 for the preparation of MECHANICAL WOOD; and in 1866 by the introduction of methods for the preparation of CHEMICAL WOOD PULP by Tilghmann, notably by the *sulphite* process. The employment of wood pulp in the papermaking industry has since been followed by its application to purposes of a very different character. The processes for converting wood into pulp are of two kinds: (1) Mechanical, in which the wood is treated by purely mechanical agencies. (2) Chemical, in which a pure form of cellulose is obtained by drastic chemical treatment.

(1) MECHANICAL WOOD PULP.—The trees suitable for the manufacture of pulp, *e.g.* poplar, fir, and pine, are felled in the early part of the winter and cut into lengths of 12, 14, and 16 ft. The logs are then conveyed to the pulp mill, where they are cut into lengths of 2 ft. by powerful circular saws, and the outer bark is removed by special machinery. The refuse is blown away and utilised as fuel, and the clean 2-ft. pieces of wood are then converted into pulp by means of grinders, *i.e.* large grindstones mounted on heavy shafts and fitted with appliances by means of which the blocks of wood are forced against the stones by hydraulic pressure. The blocks of wood are thus ground into fibrous material, and the product is mixed with large quantities of water and passed through screens—shallow boxes, the bottoms of which consist of brass plates containing very fine narrow slits. The finely screened pulp is then put through what is known as a "wet press machine," in order to remove the excess of water and convert the pulp into a thick sheet. The sheets thus obtained are folded to a uniform size, subjected to heavy pressure, packed up in suitable covering, and despatched to the paper mill.

(2) CHEMICAL WOOD PULP.—There are several processes in use for the manufacture of chemical pulp, *e.g.* the caustic soda method and the bisulphite of lime process, the latter being in general use. The following is a brief description of the sulphite process: The logs, having been barked and cut up into 2-ft. lengths, are chipped up into small pieces, about the size of a cork, by special machinery, and

then transferred to the digesters—huge steel vessels lined with bricks or cement, in which the wood is boiled under pressure with a solution of bisulphite of lime. This powerful reagent is prepared by allowing the fumes of burning sulphur to act upon moist masses of limestone, which are kept wet by a stream of water under properly regulated conditions. The digesters employed are sometimes of enormous size, capable of taking no less than twenty tons of wood at one turn. After digestion for eight to nine hours under a pressure of 80 lb., the contents of the boiler are blown out into tanks and washed thoroughly to remove the spent liquor. The weight of pulp obtained is only 50 per cent. of the original wood, so that a loss of 50 per cent. is sustained in the manufacture of the chemical wood, the by-products having little or no commercial value. The pulp after washing is screened and converted into thick sheets in the same manner as the mechanical pulp. The pulp is also obtained in the form of dry sheets by the use of a machine similar in construction and principle to the ordinary paper machine. The pulp so prepared is then ready as a raw material for other industries. The sulphite pulp is blended with mechanical pulp in varying proportions for the production of cheap printings and newspaper. A well cooked pulp gives a pure *cellulose* almost equal to that derived from rags. The marked deterioration in the quality of ordinary paper, and the lack of durability, may be traced in a very large measure to the presence of mechanical wood pulp. The durability of any paper is in direct proportion to the percentage of absolutely pure cellulose, this material being easily isolated from the best quality of rags, since the amount of chemical treatment necessary is reduced to a minimum. In the case of Mechanical wood pulp the whole of the resinous and non-fibrous constituents of the wood are present, and these constituents are liable to chemical changes, probably due to moisture and other atmospheric conditions. In the case of Sulphite wood pulp the purity of the cellulose is mainly a question of careful manipulation. One ton of ORDINARY NEWSPAPER consists of Mechanical wood pulp and Sulphite wood pulp in the proportion of 75 and 25 per cent. respectively, together with a certain proportion of mineral matter. The quantity of wood pulp required for this amount of paper is 1,680 lb. of Mechanical pulp and 560 lb. of Sulphite approximately, nearly one cord of wood being required to produce the former and about half a cord to produce the latter. A "cord of wood" consists of logs 4 ft. long, packed together so as to form a pile 8 ft. by 4 ft., giving a total capacity of 128 cubic ft. This is the usually accepted unit of measurement for pulp wood logs. It is calculated that for logs having an average diameter of 12 in., about fifty-four pieces, each 4 ft. long, will make one and a half cords, which is the quantity necessary for a ton of cheap newspaper. The number of trees required to produce this amount of wood will, of course, vary. Assuming that the trees are about 60 ft. high to the crown, then five of these trees will be necessary to produce sufficient pulp for the production of the paper.

Wood pulp is now employed as the basis of many highly interesting commercial products, which at first sight would appear to have little or nothing in common with wood. If treated with nitric acid under special conditions, nitrates of cellulose are formed which, when dissolved in a mixture of ether and alcohol, give COLLODION SOLUTION (*see* CELLULOSE *and* COLLODION), a well-known substance used in photography. Varying the conditions of nitration, as, for example, by prolonged treatment with nitric acid, other nitrated compounds are produced, and these find employment as GUN COTTON (*q.v.*), which is used in blasting. If gun cotton is incorporated with camphor by suitable mechanical means, a plastic body is produced known as CELLULOID (*q.v.*), a material capable of being moulded into a great variety of shapes, and coloured many shades. A similar product to celluloid is the well known Xylonite (*q.v.*) Then, again, by careful preparation of certain nitrates of the cellulose, and by modifying the conditions of their production, SMOKELESS POWDERS are obtained, such as Cordite, Ballistite, etc. By mixing the nitrocellulose with nitrobenzene or camphor in definite proportions, other well known explosives, such as E.C. and S.S. SPORTING POWDERS, are obtained. By treating wood cellulose with strong caustic soda, and submitting the product to the action of bisulphide of carbon, a soluble product is formed, which is extremely viscous. This viscous solution has the property of "setting" to a hard mass, and is capable of being manipulated into articles closely resembling ebony and vulcanite. The commercial applications of VISCOSE are numerous. The soluble solutions can be converted into insoluble bodies, and then employed for the manufacture of explosives. One of the most interesting applications of Wood Pulp is the manufacture of ARTIFICIAL SILK (*see* CELLULOSE). This substance is obtained by producing cellulose nitrates under special conditions and dissolving the nitrates in suitable mixtures of ether and alcohol. The viscose solution obtained is forced through extremely fine orifices into water, with the result that the solution produces an insoluble compound in the form of a thread. A number of threads are suitably twisted together and wound into the form of a hank. The resulting yarn is treated chemically in order to remove the combined nitric acid, which if left in would give a highly explosive compound, and the substance eventually obtained is a pure cellulose, capable of being dyed most brilliant colours, and endowed with a very high lustre.—R. W. S.

Woods. *Classification.*—A complete classification of woods can only be made on botanical principles. The *Coniferæ* include the great majority of those known as SOFT WOODS, which are used in general carpentry and joinery, and the practice has arisen of denominating most other timbers as HARD WOODS for trade purposes. The subjoined table gives the genus and species of various trees, followed by the name of the order (in brackets).

Preparation of Timber for the Market.—This includes (1) FELLING, (2) SQUARING, (3) SEASONING, and (4) CONVERSION. When the tree has been felled it should be roughly squared, that the air may come into contact with the wood, when the seasoning or drying process at once commences. In many cases the log is further cut in order to accelerate the process. It is then freely exposed to the air, but protected from damp and direct sun for a period which may vary from three months to two or three years, according to the kind of wood, the uses to which it is to be put, etc. ARTIFICIAL SEASONING is effected by drying with hot air, sometimes preceded

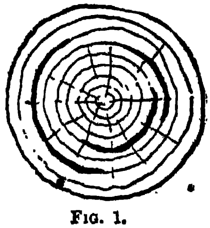


FIG. 1.

by soaking in water. CONVERSION is the sawing of the timber into the sizes required for the market; this should be followed, if possible, by further seasoning.

Defects of Timber.—SHAKES are cracks or flaws in the wood, which may have occurred during growth or which may be due to unequal shrinkage. CUP SHAKES are clefts following the annual rings (fig. 1). HEART SHAKES consist of clefts which cross the pith and widen out as they approach it (fig. 2). STAR SHAKES (fig. 3) widen towards the bark. RHIND GALLS are defects produced by growth of fresh layers over an injury sustained by the outside of the tree during growth. Local decay produces defects known as FOXINESS. WET ROT is produced by decay during growth, and is due to the attack of fungi. DRY ROT, to which timber is liable after seasoning, is also due to fungi; but the name is misleading, inasmuch as it only occurs in the presence of moisture and the absence of free circulation of air.

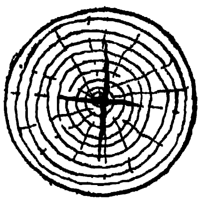

FIG. 2.

Preservation.—The first essential to successful preservation is good seasoning; but various artificial means are also very valuable. Such are CREOSOTING and KYANISING (*q.v.*) CARBONISING or charring the surface is valuable for preserving parts of timber, such as posts, buried in the ground. Impregnation with zinc chloride (BURNETT'S PROCESS, *q.v.*) and with copper sulphate are other methods, but they are inferior to creosoting.

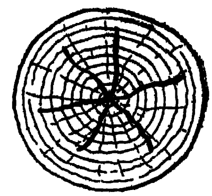

FIG. 3.

Common Names.	Botanical Name.	Localities.	Characteristics.	Uses.
Acacia (Locust)	*Robinia pseudacacia*	—	*See* LOCUST.	—
Acacia .	*Eucryphia moorei* (*Rosaceæ*)	Australia .	Fairly hard; grows to a large size	Carriage work.
Alder . . .	*Alnus glutinosa* (*Betulaceæ*)	Europe; America	Soft, light, smooth grain; light brownish tint; durable in water	Piles, sluices, and other submerged work; barrels, clog soles; also used for making charcoal for gunpowder.
Amboyna-wood	*Pterocarpus* (*Leguminosæ*)	E. Indies .	Hard, well marked, very ornamental, and capable of a high polish; colour orange to brown; scented	Inlaying and small decorative work.
Angelique .	*Dicorynia* (*Leguminosæ*)	Brazil. . .	Hard, durable in sea-water . .	Shipbuilding work.
Apple . . .	*Pyrus malus* (*Rosaceæ*)	—	Hard, heavy, brittle	Turnery.
Ash. . . .	*Fraxinus excelsior* (*Oleaceæ*)	Europe . .	Tough, flexible, fairly hard, close grain. Distinctly marked grain, light colour.	Many purposes where flexibility and toughness are essential—*e.g.* hoops, handles for hammers and other tools, shafts of vehicles, wheels; cabinet making.
Ash, American	*Fraxinus americana*	America. .	Closer, and of lighter colour, than the common Ash.	Used for much the same purpose as the common Ash.
Ash, Mountain (Rowan)	*Pyrus aucuparia* (*Rosaceæ*)	Europe, Asia	White to reddish white. . . .	Occasionally used in turnery.
Aspen. . .	*Populus tremula*. (*Salicineæ*)	Europe .	Light and soft; nearly white or slightly tinted with brown	Turnery and miscellaneous small work.
Aspen, American	*Populus tremuloides*	N. America.	Resembles the European Aspen	Turnery; wood-pulp.
Basswood .	*Tilia americana* (*Tiliaceæ*)	N. America.	Light, soft, but fairly tough and close-grained; white to light brown in colour	Turnery and miscellaneous. N.B.—The name is sometimes applied erroneously to American WHITE WOOD, or *Liriodendron tulipifera* (*q.v.*)
Beech . . .	*Fagus sylvatica*. (*Cupuliferæ*)	Europe . .	Heavy, hard, very strong and tough; colour varies from white to almost red.	Turned work, planes, tool handles, wooden screws and nuts, wheel cogs, printers' wood work. On the Continent for fuel and charcoal.

Common Names.	Botanical Name.	Localities.	Characteristics.	Uses.
Birch . . .	*Betula alba* (*Betulaceæ*)	Europe . .	Fine grain, fairly strong; colour yellowish white to brown	Furniture and turnery. The twigs are used in making hoops, crates, etc., in tanning, and for burning in smoking provisions. The bark has also been put to many uses.
Blackwood .	*Acacia melanoxylon* (*Leguminosæ*)	Australia .	Hard, even, fine grain	Ornamental work; also for casks, turnery, and miscellaneous purposes.
Blackwood, Indian	*Dalbergia* (*Leguminosæ*)	India . . .	Hard, tough, cross-grained; takes a good polish	Sleepers, and various local uses; imported for cabinet making.
Box . . .	*Buxus sempervirens* (*Euphorbiaceæ*)	Europe, Asia, N. Africa	Very close grain: hard; colour light yellow	The chief wood in wood engraving, turnery, etc.
Briar-wood (Bruyère)	*Erica arborea* (*Ericaceæ*)	S. Europe .	Small tree; heavy, brown mottled wood	Tobacco pipes. From the French name *Bruyère* is derived the common name "Briar" as applied to pipes.
Butternut (White Walnut)	*Juglans cinerea* (*Juglandaceæ*)	N. America.	Soft, but not attacked by insects	Sleepers and miscellaneous uses, in America.
Canary, American (American whitewood)	*Liriodendron* . .	—	*See* WHITEWOOD.	—
Canary-wood	*Morinda citrifolia* (*Rubiaceæ*)	E. Indies, Australia	Yellow, handsome markings, and capable of a fine polish	Turnery, cabinet work.
Cedar (true).	*Cedrus libani* . . (*Coniferæ*)	Asia . . .	Large timber, sometimes over 4 ft. in diameter. Red-brown, loose, porous, and somewhat stringy grain; soft, not tough; scented	Internal work. Well known as "Cedar of Lebanon" in ancient times; now little used.
Cedar, Deodar	*Cedrus deodara* (*Coniferæ*)	N. India . .	A very large coniferous tree; very common in N. India. Yellow to light brown; even grain; very durable	Almost all purposes in India, from bridge building and railway sleepers to delicately carved decorative work. An oil obtained from it is used as a preservative and antiseptic.
Cedar, Moulmein	*Cedrela toona* (*Meliaceæ*)	E. Indies, Australia	Colour resembles mahogany; very finely marked, straight open grain	Furniture, decorative work, veneering.
Cedar, Red .	*Juniperus virginiana* (*Cupressineæ*)	N. America.	Resembles cedar	Cabinet work, veneering.
Cedar, W. Indian (Cuban Cedar)	*Cedrela odorata* . (*Meliaceæ*)	W. Indies .	Not as large as the Cedar of Lebanon; wood much resembles the latter; often finely marked	The ordinary Cedar used in England for internal parts of cabinet work, etc.
Cherry . .	*Prunus cerasus* (*Rosaceæ*)	Europe, Asia	Yellow to light brown; hard; close grain	Ornamental work, turning.
Chestnut . .	*Castanea vulgaris* (*Cupuliferæ*)	Europe, America	Yellow to brown, fairly hard, durable	Occasionally in cabinet work; not used in carpentry and joinery; piles and fencing.
Chittagong-wood	—	—	Various ornamental woods from India—*e.g.* Moulmein Cedar (*q.v.*)	Decorative work.
Cypress . .	*Cupressus* (*Cupressineæ*)	S. Europe, Asia	Red colour; fragrant; very durable	Used chiefly by the ancients.
Deal . . .	*Pinus*	—	*See* PINE.	—
Deodar . .	*Cedrus deodara* (*Coniferæ*)	—	*See* CEDAR, DEODAR.	—

Common Names.	Botanical Name.	Localities.	Characteristics.	Uses.
Douglas Fir. (Oregon Pine)	*Pseudotsuga douglasii* (*Coniferæ*)	N.W. America	A very large tree; yellow to reddish; very hard, dense, strong; straight grain	Spars, masts; in America for building and engineering work; use increasing in England.
Ebony	*Diospiros ebenum* (*Ebenaceæ*)	India	Large tree, very dense; heart-wood very black	Ornamental work, turning, inlaying.
Elder	*Sambucus nigra* (*Caprifoliaceæ*)	Europe, etc.	Stem hollow, with a large amount of pith	Little used, except to a small extent in turning.
Elm, American	*Ulmus americana* (*Ulmaceæ*)	N. America	Tough and heavy wood	Miscellaneous uses in America.
Elm, English	*Ulmus campestris*	Europe	Brown to red; hard, heavy; difficult to work on account of the twisted grain; very durable	Piles, and other work embedded in the ground; pulley blocks, wheel hubs, shipbuilding.
Elm, Wych	*Ulmus montana*	N. Europe	Softer and straighter in grain than common elm	Chairs, shafts of vehicles.
Fir	—	—	A term applied to many timbers obtained from the *Coniferæ*. *See* LARCH, PINE, SPRUCE.	—
Fir, Silver (Swiss Pine)	*Abies pectinata* (*Coniferæ*)	S. Europe	Yellowish; very soft and easy to work	Toy making and miscellaneous uses in Switzerland; parts of musical instruments (*e.g.* bellies of violins, etc.).
Greenhart	*Nectandra rodæi* (*Lauraceæ*)	W. Indies	Green to black; heavy (*Sp. Gr.* 1·08 to 1·2), tough; very straight grain; durable	Shipbuilding, piles, wooden bridges.
Gum, Black	*Nyssa multiflora* (*Cornaceæ*)	N. America	Yellow to brown; tough, cross-grained	Miscellaneous local uses.
Gum, Blue	*Eucalyptus saligna*	Australia	Brown to red, cross-grained, heavy, durable	Sleepers, posts, building work in Australia.
Gum, Red	*Eucalyptus* (*various species*)	Australia	Red, hard, very durable	Paving and miscellaneous uses in Australia. Often confused with JARRAH (*q.v.*)
Gum, Sweet (Red Gum, Satin Walnut)	*Liquidambar styraciflua* (*Hamamelaceæ*)	United States	*See* SATIN WALNUT.	—
Gum, Tasmanian	*Eucalyptus globulus*	Tasmania, etc.	Resembles the Blue Gum, but somewhat easier to work	Uses similar to Blue Gum.
Hawthorn	*Cratægus oxyacantha* (*Rosaceæ*)	Europe, Asia	Small size; hard, heavy, light-coloured	Turnery.
Hazel	*Corylus avellana* (*Cupuliferæ*)	Europe	Small; soft, very flexible	Hoops, walking-sticks.
Hickory	*Hicoria* (*Juglandaceæ*)	N. America	Heavy, hard, very tough and elastic	Carriage building, hoops, and various work which has to withstand bending. In Australia the name is applied to other woods, *e.g.* various species of Acacia.
Holly	*Ilex aquifolium* (*Ilicineæ*)	Europe, W. Asia	Nearly white; very fine smooth grain	Ornamental work, and for engraving.
Hornbeam	*Carpinus betulus* (*Corylaceæ*)	Europe	Light colour; hard, strong	Tool handles and miscellaneous uses.
Horse-chestnut	*Æsculus hippocastanum* (*Sapindaceæ*)	Europe, Asia, N. America	Light colour; soft, not very durable.	Miscellaneous; little used in carpentry and joinery.
Ironwood	—	—	A name loosely applied to a variety of woods: *e.g.* various species of *Acacia* in Australia, and to certain members of the order *Myrtaceæ*	—
Ironwood, Black	*Olea laurifolia*	S. Africa	Large tree; very hard, durable.	Waggon building.

Common Names	Botanical Name	Localities	Characteristics	Uses
Ironwood, White	*Toddalia lanceolata*	Natal	Pale yellow colour, durable, tough	Building work in Natal.
Ironwood, White	*Sideroxylon inerme* (*Sapotaceæ*)	E Coast of Africa	Hard, heavy, and durable, yellow to red-brown	Shipbuilding and miscellaneous
Jarrah	*Eucalyptus marginata* (*Myrtaceæ*)	Australia (S W)	Large tree, colour resembles mahogany, often having a curled and handsome grain polishes well, and very durable under almost any conditions The most important of Australian woods	Wood paving, shipbuilding, general building and engineering work; the well-marked varieties are used to some extent for furniture and cabinet making
Juniper	*Juniperus communis* (*Cupressineæ*)	Europe, N Asia, and N America	Small tree light colour, soft	Miscellaneous, not important
Karri	*Eucalyptus diversicolor* (*Myrtaceæ*)	Australia (S W)	Large tree, heavy, tough, hard, durable, though inferior in this respect to Jarrah	Paving shipbuilding, and other uses similar to those of Jarrah
Kauri	*Agathis australis* (*Araucarineæ*)	New Zealand	A resinous, light-coloured straight grained wood, very durable and working well The chief timber of New Zealand, where it is often termed KAURI PINE	Masts, shipbuilding, building
Lancewood	*Guatteria virgata* (*Anonaceæ*)	S America	Straight grained tough, and elastic	Shafts of vehicles, fishing rods, and light work requiring flexibility
Larch	*Larix europæa* (*Abietineæ*)	Europe, N Asia	A large tree when fully grown, loose grained, soft wood, durable	Poles and ladders, fencing, mine timbering, piles, to some extent in general carpentry and joinery
Lignum-vitæ	*Guaiacum officinale* (*Zygophyllaceæ*)	W Indies	Dark coloured, very heavy, hard and cross grained, exceedingly durable	Miscellaneous small work, turnery etc, where hardness and freedom from splitting under rough usage are required
Lime (Linden)	*Tilia* var species (*Tiliaceæ*)	Europe	White to yellow, soft and close grained	Turnery, carving, piano making
Locust	*Hymenæa*	W Indies	Brown, hard, even grain	Shipbuilding, furniture, miscellaneous
Locust	*Robinia pseudacacia* (*Leguminosæ*)	United States Europe	Very heavy, tough, hard wood A familiar ornamental tree of small size in England, attaining a height of 70 or 80 ft in America	Fencing, turnery, cabinet work Often termed Acacia
Mahogany	*Swietenia mahagoni* (*Meliaceæ*)	W Indies, Central America	Hard, close grain grain straight but often showing a wavy or curly figure, characteristic reddish brown colour Very durable, free from shakes and not liable to warping Can be obtained in very large logs, in some cases over 4 ft square	Furniture cabinet making, veneers, turnery, high-class internal joinery and fittings
Maple	*Acer* (*Acerineæ*)	Europe, North Asia	Light brown or reddish, often showing a curled or mottled figure, whence the name "Bird's Eye Maple	Turnery, veneers, various cabinet and ornamental work
Mulberry	*Morus alba* (*Moraceæ*)	Europe, Asia	Yellow to mahogany-red, hard, close grained	Veneering and ornamental work
Myrtle (Spurious)	—	—	The name is applied in Australia to a number of woods of small importance, none of these are true myrtles.	—

Common Names.	Botanical Name.	Localities.	Characteristics.	Uses.
Oak . . .	*Quercus* (*Cupuliferæ*)	Northern Hemisphere	The most important of all hard woods. Colour light greyish yellow to dark brown. Hard; very strong grain, often showing a handsome figure, that obtained by cutting a log in a radial direction being termed the "Silver Grain." Very durable; capable of taking a high polish	Heavy work requiring great strength and durability: piles, shipbuilding, building work, especially such parts as are exposed to the weather, furniture, and a great variety of other uses.
Olive . . .	*Olea Europæa* (*Oleaceæ*)	S. Europe .	Very close-grained, yellowish, somewhat resembling Box	Turnery and small articles.
Padouk . .	*Pterocarpus* (*Leguminosæ*)	S.E. Asia .	Hard, heavy, dark red, somewhat like mahogany; not attacked by insects	Furniture and miscellaneous uses in India and Burma.
Peach . . .	*Amygdalus persica* (*Rosaceæ*)	—	—	Widely distributed; little used as timber.
Peach-wood .	*Cæsalpina* (*Leguminosæ*)	S. America .	Small tree; hard heavy wood	Source of a dye.
Pear . . .	*Pyrus communis* (*Rosaceæ*)	Europe, Asia	Even grain, fairly hard; colour light brown; durable	Turnery, T-squares and set-squares, occasionally for cabinet work.
Pine . . .	*Pinus* (*Coniferæ*)	Northern Hemisphere	The general name Pine is given to a great number of woods obtained from trees of the order *Coniferæ*; to certain of these the names Deal and Fir are applied. The wood is resinous, usually fairly soft, straight-grained, and easy to work	Building work, and a great variety of miscellaneous carpentry and joinery.
Pine, Kauri .	—	—	*See* KAURI.	—
Pine, Long-leaf	*Pinus palustris* .	N. America .	The PITCH PINE of commerce. One of the harder varieties of pine; very resinous; strongly marked grain, often showing a very fine figure; durable	Building, furniture, spars, shipbuilding.
Pine, Northern	*Pinus sylvestris* .	N. Europe and N. Asia. The Baltic regions are the chief source	SCOTCH FIR, RED or YELLOW DEAL; includes much of the FIR of commerce. Yellow to slightly reddish; straight-grained, and obtainable in long logs. Somewhat variable, according to locality and conditions of growth	Building, spars, etc.; a vast amount of general carpentry and joinery. It is the most important wood used in this country.
Pine, Oregon	*Pseudotsuga* . .	N.W. America	The DOUGLAS PINE or FIR. Very similar in character to Larch; straight-grained; yellow to reddish, usually darker than Northern Pine; can be obtained in very long logs	Masts and spars, general building work in America, and now coming rapidly into use in England.
Pine, Pitch .	—	—	*See* PINE, LONG-LEAF.	—
Pine, Red .	*Pinus resinosa* .	N. America .	CANADIAN RED PINE. Hard, tough, reddish; contains much resin, and is very durable	Spars, building.
Pine, Swiss .	*Abies pectinata* .	Central Europe	Light, soft; very little resin; easily worked	Piano soundboards, violin bellies, miscellaneous purposes.
Pine, White .	*Pinus strobus* . .	N. America .	Also known as Yellow Pine. Soft, straight-grained; does not contain resin	Building and miscellaneous uses, especially in America.
Plane, Eastern	*Platanus orientalis* (*Platanaceæ*)	Asia and E. Europe	Yellow to brown; fine close grain, but not durable	Miscellaneous uses; not very important in England.

Common Names.	Botanical Name.	Localities.	Characteristics.	Uses.
Plane, Western	*Platanus occidentalis*	N. America.	Resembles the above, but coarser and more cross-grained	Furniture, veneers, and miscellaneous uses.
Plum . . .	*Prunus domestica* (*Rosaceæ*)	Europe, Asia, etc.	Yellow to brown, hard, not durable	Turnery, cabinet work.
Poplar . .	*Populus* (*Salicineæ*)	Europe, Asia	Soft, light colour, not liable to split	Turnery, paper-pulp, charcoal.
Redwood . .	—	—	A name applied to various woods—*e.g.* a variety of Eucalyptus in Australia, and to Northern Pine (*q.v.*)	—
Redwood, Californian	*Sequoia* . . .	West of N. America	Orange to red; soft, not strong, but withstands the action of soil; easily split. Known in England as *Sequoia*	Building and general purposes in California; used in England for furniture.
Rosewood .	—	—	A variety of woods of dark colour are known by this name. None of them belong to the Rose family.	—
Rosewood, Brazilian	*Dalbergia* (*Leguminosæ*)	America .	Dark brown to red, open-grained, heavy	Cabinet making, turnery, and ornamental work.
Sandalwood .	*Santalum* (*Santalaceæ*)	S. Asia . .	Yellow, fragrant, hard wood	Ornamental work, and as a source of sandalwood oil.
Satin Walnut	*Liquidambar styraciflua* (*Hamamelaceæ*)	East of U.S.A.	Reddish brown, soft, close grain; easy to work, polishes well, but very liable to shrinkage and warping	Much used for the cheaper varieties of polished cabinet work and furniture.
Satinwood .	*Chloroxylon* (*Meliaceæ*)	S. India . .	Orange yellow, finely marked, polishes well, fairly durable	Ornamental work.
Sequoia . .	—	—	*See* REDWOOD.	—
Spruce . .	*Picea excelsa* (*Coniferæ*)	N. of Europe, Asia, and America	WHITE DEAL, SPRUCE FIR, WHITE FIR. White to yellowish, soft, straight grain; easy to work, but apt to warp	Poles and spars, flooring, general carpentry; also as a source of wood-pulp, charcoal, and resin.
Sycamore . .	*Acer pseudo-platanus* (*Acerineæ*)	Europe and W. Asia	Very white, soft, easily worked, polishes well; durable if not exposed to damp	Turnery, carved work, cabinet work, violin making, and miscellaneous uses.
Teak . . .	*Tectona grandis* (*Verbenaceæ*)	S. Asia . .	Brownish red, hard, tough, often finely marked, very fragrant. It is somewhat difficult to work on account of particles of mineral matter; extremely durable, probably more so than any other timber	Shipbuilding, heavy timber work.
Tulip Tree .	—	—	*See* WHITEWOOD.	—
Tulip-wood .	*Harpullia pendula* (*Sapindaceæ*)	Australia .	Black and yellow markings; tough and strong (The name Tulip-wood is also applied to two or three other ornamental woods of less importance)	Ornamental cabinet work.
Walnut . .	*Juglans regia* (*Juglandaceæ*)	Europe, Asia	Light to very dark brown, often finely marked; strong, hard, durable; polishes well	Cabinet making, furniture, veneers, turnery, gunstocks.
Walnut, Satin	—	—	*See* SATIN WALNUT.	
White Deal .	—	—	*See* SPRUCE.	—
Whitewood .	*Liriodendron tulipifera* (*Magnoliaceæ*)	N. America.	White, slightly tinged with yellow; very soft and easily worked; fairly durable, but liable to shrinkage; takes stains and polishes well. Can be obtained in large logs and wide boards, very free from knots	Building work, cabinet making, carriage building, and general joinery. Rapidly becoming a very important wood in this country.

Common Names.	Botanical Name.	Localities.	Characteristics.	Uses.
Willow . .	*Salix* (*various species*)	Europe, N. America	White, soft, smooth grain; very little tendency to split or splinter; withstands the action of water well	Floats of water-wheels, etc.; brake blocks, small carving, and toys, cricket bats; wood-pulp, charcoal. Thin shoots are used extensively for basket work, hurdles, etc.
Yew . . .	*Taxus baccata* (*Taxineæ*)	Europe, Asia, N. Africa	Reddish, very hard, tough, flexible	Chairs, turnery, walking-sticks, etc. Formerly used for archers' bows.

Wood Screw. A screw (*q.v.*) of conical form, having a V-thread of coarse pitch but small thickness, and a point by which it is enabled to penetrate wood. Usually made of steel or brass.

Wood Sleepers (*Civil Eng.*) In Europe sleepers are usually of Baltic pine, soaked in creosote. Hard woods are, however, preferable where they can be obtained cheaply, and in America certain varieties of oak have been largely used. *See* RAILWAYS.

Wood Spirit (*Chem.*) A mixture of methyl alcohol, acetone, allyl alcohol, and a number of other substances present in smaller quantities. It is largely used in the preparation of methylated spirit, which contains 10 per cent. The method of obtaining it is given under methyl alcohol (*q.v.*) *See also* TAR.

Wood Tin (*Min.*) *See* CASSITERITE.

Wood Turning. Wood is still in the majority of cases turned by means of hand tools, though the lathe itself is usually driven by power in large shops. For soft wood, gouges and chisels with acute cutting edges are the principal tools used; for hard woods, tools with more obtuse edges, resembling those used in brass turning, are employed. In special cases a slide rest may be used, and in certain kinds of repetition work automatic lathes are of great value. *See also* LATHE *and* TURNING TOOLS.

Woodwardite (*Min.*) A hydrous sulphate of copper and alumina, found in Cornwall. It occurs as a brilliant turquoise blue incrustation with a rippled surface.

Wood Wind (*Music*). A term applied to the group comprising the flutes, oboes, clarionets, and bassoons in the orchestra.

Woodworking Machines. A great variety of machines are employed for woodworking on a large scale. PLANING MACHINES are of two classes. In the larger class, cutting tools are mounted upon a revolving block (ADZE BLOCK) or disc, which is caused to rotate at a high speed while the wood travels past the cutter. In the other form the cutter resembles a plane iron, and is fixed in position, while the wood is moved past it in a manner analogous to the planing machines used for metal. MOULDING MACHINES have a revolving head, or cutter block, carrying suitably shaped cutters. Other machines include various forms of LATHE, machines for MORTISING, BORING, DOVETAILING, SANDPAPERING, and various special purposes. Many forms of saw are used, of which the principal types are given on p. 643.

Woof (*Weaving*). *See* WEFT.

Wool, Woollen, and Worsted Manufacture. The manufacture of woollen cloth is one of the oldest of the national industries. Historical evidence shows that the carding and spinning of wool and the weaving of woollen yarns was practised by the Romans, and it is probable that these arts were fostered at Winchester and other places in the south. The industry received a stimulus during the persecution of the Huguenots and the importation of the Flemish weavers into this country in the sixteenth century. Still, up to the end of the eighteenth century the manufacture of all classes of fabrics was chiefly a manual process. The transformation from this period to that in which machinery was gradually invented and applied to almost every branch of textile production occurred between the last decade of the eighteenth century and the first three decades of the nineteenth. Like many other industries, the manufacture of woollen and worsted fabrics has been greatly influenced by mechanical inventions. The more important of these have been originated and perfected by British manufacturers and machinists. The Carding machine, Spinning frame, Power loom, and the mechanism for finishing and pressing the cloth after weaving, have all been English or Scotch inventions. Since 1875 Germany, France, Belgium, and America have made rapid progress in the construction and building of textile machines. In the woollen and worsted industry, however, the machinery of English makers is still in high repute on the Continent, and is almost solely used in the mills of the United Kingdom. In other words, whilst machinery constructed in this country is exported to the woollen and worsted centres on the Continent, that of German and French firms, with the exception of milling machinery and one or two types of finishing machines, has failed to obtain a place in British factories, and even these have only been used to a small extent. WOOLLENS AND WORSTEDS: The trade in fabrics made of wool is divisible into two sections, termed woollen and worsted respectively. To the uninitiated the difference is not obvious, especially when it is considered that the same variety of wool, and the same quality, may be used in both manufactures, but with totally different results. The early distinction was that a longer staple of wool was required in making *worsted* yarns; but the invention of Noble's combing machine, and the many improvements added to its construction, have removed the cause for this differentiation, and it is now feasible to deal with wool of a comparatively short staple on the worsted, as well as on the woollen system of yarn manufacture. The grading of the material into woollen and worsted is due to the routine of yarn manufacture practised. Briefly defined, the blending, carding, and spinning machinery for treating wool in making

a WOOLLEN YARN results in all kinds of fibres—curly, short, and of various lengths—entering into the spun thread. Moreover, these fibres, which in carding undergo a certain measure of combing or straightening between the wire teeth of the card clothing on the cylinders, are recrossed and blended without any attempt at parallelisation. As regards WORSTED YARN, on whatever system it may be made, and even though carding may form one of the processes, the chief object is to bring the fibres as far as possible into a line with each other by combing, etc. Another element which accentuates the difference between the two threads is that in the combing process a quantity of the short, neppy fibre is extracted, so that only the straighter and longer fibre passes into the top, and subsequently into the roving and the yarn. A comparison of the condition of the materials of these two typical threads, when carded and combed, shows that the fleece of fibres in both instances possesses uniform density and adhesiveness; but in all other points it differs. In the *carded state* the fibres are crossed in every conceivable way, but in the *combed state* they are straight and parallel. The top (combed wool) when opened out is found to be very free from curly and neppy clusters of small fibres, and subsequent processes further level and straighten the ribbon of fibres, which attain a degree of parallelism that would appear impossible by mechanical routine when the matted, felted, natural state of the wool is considered. It is, therefore, the YARN STRUCTURE which forms the distinction between woollen and worsted fabrics. The processes of weaving and finishing through which each yarn passes do not necessarily bring about any differentiation between the fabrics produced. That is to say, if the wool were treated on the woollen and worsted principles, and made into yarns of similar counts or diameters, and each made into the same build or structure of fabric and submitted to similar finishing routine, yet the woven textures would in character be very distinct from each other. The WOOLLEN CLOTH would be denser, warmer in the wear, and apparently the closer structure. This arises from not having removed any of the short fibre from the staple of the wool. On the other hand, the WORSTED would be smarter, brighter, and have a better appearance. There are more points of resistance to the friction of wear on the surface of a woollen than on a worsted cloth, and this is one of the chief reasons why the worsted has a greater tendency to become shiny or bright wherever it is subjected to friction. These general characteristics apply to all kinds of woollen and worsted cloths for whatever purpose manufactured. Woollen cloths are made in all weights from 7 or 8 oz. up to 32, 34, and even 36 oz. per yard (54 and 56-in. wide) for the heavier types of overcoatings. There is not the same diversity of weight in worsteds. Fashion has removed the great lines of demarcation between fabrics for men's and women's wear. Only a few years ago the dress trade was distinctly an alpaca or mohair manufacture. Such fabrics are still produced, but are now largely substituted by woollen and worsted costume cloths of Cheviot, Saxony, crossbread, and Botany yarns.

Routine of Manufacture for Woollens.—This can only be very briefly summarised. The wool, in the first place, is sorted or classified as to quality. It is naturally in a greasy condition, the ordinary English crossbred wool averaging 25 to 35 per cent. of greasy matter; but the fine merino wools, such as Saxony, Australian, and New Zealand, as much as 60 per cent. and more. This is removed by scouring in large tanks or bowls, usually three or four in number, after which the wool is passed through a machine known as the teazer, which separates the matted locks of fibres and prepares it for carding. Should the material be for coloured yarns, after scouring the wool is dyed, in which case teazing both disentangles the locks of wool and blends the colours together, producing a mixture. It is now carded. CARDING consists of passing the wool between fine wire teeth on a series of large cylinders. Over these are a number of smaller rollers similarly covered, the function of which is, first, to impede the forward progress of the wool, and, second, in conjunction with each other and the quickly revolving cylinder, to fully open out the staple, ultimately separating fibre from fibre. At the same time, re-blending or re-crossing of the filaments continues. The work is, therefore, twofold in character: first, to dislocate the natural positions of the fibres in relation to each other; and, second, to re-cross, mix, and work them into a fleece of continuous length and similar density throughout. Attached to the last cylinder of the carder is what is termed a condenser, which removes the fleece from the cylinder, and then divides it into narrow strips which may be rubbed or rolled into thick, soft threads. SPINNING: These are taken to the spinning frame, known as the Mule Jenny, and spun into yarn. The process consists in intermittently delivering lengths of the condensed thread or sliver from large bobbins by passing them between a pair of rollers and attaching them to spindles fixed in a carriage or frame travelling alternately to and from the fixed rollers. Lengths of sliver are, first, delivered whilst the carriage makes a portion of the outward traverse, the spindles at the same time revolving. The rollers cease to turn, but the carriage continues its movement, and the speed of the spindles is increased. During this period drafting or attenuation of the thread is effected as twist is inserted. The carriage having reached the termination of its traverse, the spindles continue to revolve for the final twisting. As the carriage reverses its traverse, the threads are held in a suitable position to be wound in a conical form on the spindle. WEAVING is the next operation, and is the same in principle in both woollen and worsted fabrics. The yarns are first warped or arranged after a prescribed pattern and length, and wound on to the loom roll or beam. Before weaving can be accomplished the threads are drawn through small metal eyes of the heald shafts or heddles. These shafts rise and fall when the loom is in operation, each lifting or depressing a series of threads in the warp, making a division termed the "shed." The shuttle carrying the weft passes between the lifted and depressed yarns. For each pick or thread of weft conveyed by the shuttle the healds change positions. The weaving of a piece of cloth is the repetition of a certain series of changes, according to the number of picks in each round of the weave or design. The yarns which form the length of the cloth are, therefore, complete at the beginning of weaving; but the weft is added thread by thread, forming a woven piece. The routine after weaving consists of scouring, milling, or felting, and in some instances raising—that is, covering the cloth with fibre, cutting, removing the surface fibre, and pressing.

Routine of Worsted Yarn Manufacture.—The worsted industry consists of two distinct sections: (*a*) The manufacture of the yarn and (*b*) the manufacture

and finishing of the fabric. In this respect it differs from the woollen industry, which is usually carried on throughout the whole range of manufacturing in one factory. This departmental division has, in a measure, contributed to the success of this important branch of the all wool industry. A section of the trade has thus been confined to producing economically every variety of yarn, and another section to the manufacture of the woven texture. Consider first the PRODUCTION OF THE YARN. There are three distinct methods: (*a*) By the processes of carding, combing, gilling, drawing, roving, and spinning, resulting in the fine Botany and also crossbred yarns used in the manufacture of worsted coatings, suitings, trouserings, and costume fabrics. (*b*) For long wools, preparing by gilling and following with a similar series of operations. (*c*) The first routine, with the exception of combing. This produces a yarn which has some of the qualities of a worsted and some of a woollen thread, and is suitable for Scotch and Kidder carpets. COMBING is the process by which the carded or gilled wool is straightened, and the fibres laid in one common line. This is done by forcibly drawing the wool between fine teeth, and delivering it in a continuous ribbon of fibres, known as *top*. Part of the work also consists in extracting short, curly fibre, which is termed the "noil," so that the top is free from much of that neppy filament which is seen in the carded wool. The machines on which the work is done are known as the Noble, the Square Motion, and the Nip Combs. Whilst very different in construction and working, the results acquired are similar. GILLING is performed in the gill boxes, which possess two pairs of rollers, front and back, revolving at different speeds. Between these are placed the fallers, iron bars studded with fine vertical teeth, and which travel from the front to the back rollers at a higher speed than the feed rollers, but slower than the delivery rollers. Reaching the end of the forward traverse, they drop on to a lower screw, and are conveyed back to the front rollers, and replaced on the upper screw. The wool passing between the first pair of rollers is drawn between the teeth of the fallers by the delivery rollers. In other words, there is a drafting or drawing out of the wool at two points by the fallers from the front rollers, and by the delivery rollers from the fallers. The fibres of wool are thereby further straightened and parallelised. DRAWING: In the first drawing boxes a similar process continues as in gilling, several ribbons of wool being drawn out to the thickness of one. In the finishing drawing boxes the fallers and gill pins are not used, but several thick ribbons of fibres are combined and attenuated to the thickness of one, and further reduced in size at each box, and wound on to smaller bobbins each time, until the roving box is reached, where the material begins to assume the form of a thread, which by twist can be converted into a fine weavable yarn. SPINNING: This is different from the operation performed on the mule spinning frame used in making woollen yarn. It is on what is known as the "continuous" system; that is to say, the thread is continuously delivered and spun, not intermittently. The rovings pass between two pairs of rollers revolving at various speeds, where further drafting takes place, and are spun into yarn on three systems. First, the Flyer, which is similar in principle to the distaff or single spinning wheel, only the spindle and flyer are in a vertical instead of a horizontal position and duplicated a large number of times. Second, on the Cap Frame, where the bobbin is covered with a metal cap and the thread rapidly revolves round the lower rim of the same as it is spun and wound on to the bobbin. Third, on the Ring Frame, in which a small ring or "traveller" is placed on a metal rim and guides the thread during spinning on to the bobbin. WEAVING: The industry is divided into the spinning and weaving of (*a*) Long wools, such as those grown in Leicestershire and Lincolnshire, suitable for dress and mantle fabrics; (*b*) Crossbred, a coarse stapled wool, such as that grown in many parts of Great Britain and Ireland, and also largely imported from the Colonies and made into serges and dress fabrics; (*c*) fine wools of the Botany type, principally from Australia, the Cape, and South America, and which are used in the medium and finest qualities of worsted fabrics. Worsted fabrics comprise a very wide range of woven productions. Broadly speaking, they may be classified under two heads, namely, PIECE DYE and FANCIES. As the term suggests, the former are dyed in the piece, and are usually coatings, suitings, and costume cloths. Fancies are top or yarn dyed; that is to say, the pieces are made of yarns in which the material has either been dyed after combing or after it has been spun into the yarn, the first being the most usual practice. Fancies, in addition to the fabrics named under piece dyes, also include many varieties of dress and blouse materials, vestings, trouserings, and covert coatings, all of which are capable of many subdivisions. *A feature about worsted fabrics, as distinguished from the woollen, is the diversity of weave design obtainable.* It follows that they are richer in technical weave effects, and also clearer in colour than the patterns produced in woollen yarns. Many Scotch tweed manufacturers, whose trade was formerly confined to suiting cloths, or what may be more correctly defined "men's" fabrics, now run in the same mill many varieties of textures for costumes, vestings, suitings, etc. The worsted trade is more departmental, one cause being that a much lighter construction of loom, and one capable of a higher speed is employed, being better adapted for the weaving of worsted dress and costume fabrics than the loom used in the suiting and trousering trade. The chief centres of the different branches of the industry are: For the FINE WORSTED TRADE: Huddersfield, Leeds, Bradford, Halifax, and the west of England, though some worsted manufacturing is also done in the border towns of Scotland and in the south of Ireland. The TWEED industry is chiefly located in the south of Scotland and Wales; a medium quality of tweed is also made in the West Riding of Yorkshire. Fine SAXONY CLOTHS are produced in the west of England and the West Riding of Yorkshire; FLANNELS in Yorkshire and Wales; BLANKETS AND RUGS in the Dewsbury and Sowerby Bridge districts; and the low woollen industry for ready made clothing is carried on in the West Riding at Batley, Dewsbury, Morley, etc. It should, however, be observed that these divisions are not always strictly adhered to, as there are some mills engaged upon fancy woollens, fine worsteds, and serges in each of these centres.—R. B.

Woolwich and Reading Beds (*Geol.*) The middle division of the Lower London Tertiaries. *See* STRATA, TABLE OF (in Appendix).

Worcester (*Pottery*). The Worcester porcelain works were established in 1751, by Dr. Wall, of Worcester. In 1783 the business was purchased by

Mr. Flight, and subsequently passed through the following periods: 1793, Flight & Barr; 1807, Barr, Flight & Barr; 1813, Flight, Barr & Barr. In 1840 the manufactory was united with that of Messrs. Chamberlain, a rival factory in Worcester. The manufactory is carried on by the present Royal Porcelain Company, and it is the only Porcelain Works in England with an unbroken record of more than 150 years. Worcester has been noted for producing a greater variety of designs, etc., than any other porcelain manufactory, commencing with simple blue and white wares, up to services and vases decorated, painted, and gilt in the most costly manner, combined with judgment and taste.

Work (*Mech.*) If a force be so applied as to overcome a resistance and produce motion, it is said to do Work. The measure of the work done is the product of the force into the displacement which it effects. If a force of one Dyne act through a distance of one centimetre, the amount of work done is termed one ERG. If a force of one poundal act through one foot, the work done is one FOOT POUNDAL. If a force equal to the weight of one pound act through a distance of one foot, the work done is one FOOT POUND. The latter is the English engineer's unit of work.

Working (*Mining*). A general term used either for a mine as a whole or for some part thereof, *e.g.* a level, drift, stope, etc.

Working Cylinder (*Eng.*) The cylinder of a gas engine, etc., in which the actual explosion occurs, as distinguished from a separate cylinder used for the purpose of compressing the charge.

Working Drawing. A drawing showing the details and dimensions necessary for workmen engaged in the construction of the object in question.

Working Face (*Mining*). The surface which is actually being excavated.

Working Fat (*Plast.*) A term used by plasterers to indicate that the plaster works smoothly (with less labour).

Working Load (*Eng., etc.*) The load to which a machine or structure is subjected in ordinary use.

Worm (*Eng.*) A coarsely cut screw, usually engaging with a WORM WHEEL (*q.v.*)

Worm Wheel (*Eng.*) A form of gear wheel whose teeth are cut in such a form that they engage smoothly with a worm or coarse threaded screw. The latter has in general its axis at right angles to the wheel, which it drives.

Worsted Manufacture. *See* WOOL.

Wraithe (*Textiles*). A coarse reed or comb (which will expand or contract), used in the beaming or warping processes.

Wrapping Papers. These are prepared from chemical wood pulp, jute, or manilla.

Wrench (*Eng., etc.*) A SPANNER (*q.v.*), usually having adjustable jaws.

Writing *or* **Printing Telegraph.** *See* TELEGRAPHY.

Wrong Fount (*Typog.*) Letters of a different "face," though of the same body. *See p.* 566, EXPLANATIONS.

Wrong Gait (*Lace Manufac.*) When a carriage becomes diverted from its true course and is forced into an adjoining groove or comb that is already occupied.

Wrought Iron (*Met.*) *See* IRON.

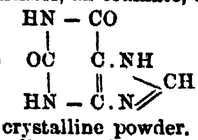
Wulfenite (*Min.*) Molybdate of lead, $PbMO_4$. Tetragonal; yellow to brown. Scotland and Central Europe.

Wyvern, Wivern (*Her.*) An imaginary beast, a species of dragon but having only two legs and feet or claws. It has also two wings, and a tail like a serpent "nowed" and "barbed."

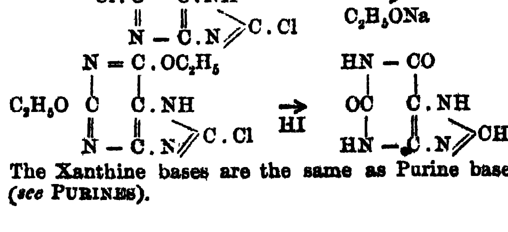
X Rays. Röntgen Rays: *see* RADIATION, *p.* 592.

x. The symbol used in mathematics for an unknown quantity, a variable, an ordinate, etc.

Xanthine (*Chem.*)

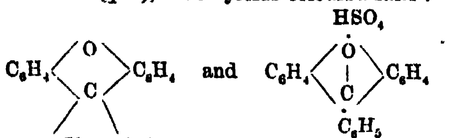


(2:6-dioxypurine). Ordinarily forms a crystalline powder. It can be obtained in very small rhombic plates by addition of acetic acid to a hot dilute alkaline solution. It sublimes without melting, but with decomposition. Very slightly soluble in water (about 1 in 14,000), more soluble on boiling, insoluble in alcohol. As a weak base it forms salts with strong acids, and the salts are hydrolysed by water. As a weak acid it dissolves more readily in alkalis (ammonia, caustic potash) than it does in water, forming salts with them. Its lead salt yields theobromine (*q.v.*) with methyl iodide. Xanthine is precipitated from its solutions both by phosphotungstic and phosphomolybdic acids; it is also precipitated by mercuric chloride solution. It forms a salt with silver nitrate, $C_5H_4N_4O_2AgNO_3$, when a solution of its nitrate is precipitated with silver nitrate. When dissolved by warming in fresh chlorine water, evaporated to dryness, and the residue exposed to ammonia gas under a bell jar, it gives a rose to purple red colour, which changes to blue violet on adding caustic soda (Weidel's test); dissolved in hot nitric acid and evaporated it gives a yellow residue (whence the name Xanthine), which is turned to orange by caustic soda. Xanthine occurs in normal urine in traces (Krüger and Salomon obtained 13 grams from 10,000 litres of human urine); in larger amount in certain diseases. It is formed by the self-digestion of several organs of the body—liver, thymus, suprarenal; also by the self-digestion of yeast. It is also found in several foods (tea, malt), in lupin seeds and pumpkin seeds. It is obtained from guanine by the action of nitrous acid. It has been synthesised as follows: 2:6:8-trichlorpurine (*see* PURINES) is heated with excess of sodium ethoxide at 100°, when 2:6-diethoxy-8-chlorpurine is obtained. This compound may be hydrolysed by boiling with hydrochloric acid, and the product reduced with hydriodic acid, or it may be reduced with hydriodic acid:



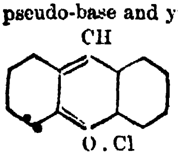
The Xanthine bases are the same as Purine bases (*see* PURINES).

Xanthones (*Chem.*) (Dibenzopyrones.) Xanthone itself,  , is a white crystalline solid (needles); melts at 174°; boils at 250°; insoluble in water; sparingly soluble in alcohol; more soluble in benzene; dissolves in concentrated sulphuric acid, showing a blue fluorescence. Fused with caustic potash at 200° it yields orthodioxybenzophenone, $CO(C_6H_4OH)_2$. It does not yield a hydrazone or oxime. On treating it with magnesium phenylbromide and hydrolysing the product it yields a pseudo-base (*q.v.*), which yields coloured salts :



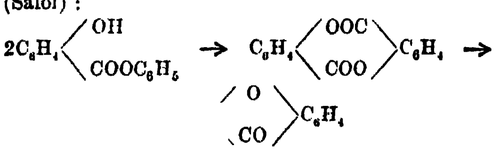
Pseudo-base. Coloured Sulphate (Quadrivalent oxygen).

On reduction with zinc dust xanthone yields xanthhydrol,  , which is also a pseudo-base and yields coloured salts with acids, *e.g.*



Hydrochloride. (Quadrivalent oxygen.)

Xanthone is obtained by distilling phenylatecylate (Salol) :



It is also obtained by heating salicylic acid with acetic anhydride, the reaction being quite similar to the above, salicylide being formed first. Euxanthone is 1 : 7-dioxyxanthone—a yellow solid crystallising in needles and melting and subliming at 237°. It occurs in the pigment Indian yellow (*q.v.*), which is the magnesium salt of euxanthic acid. Euxanthic acid is a compound of euxanthone and glycuronic acid. The pigment is obtained as a deposit by heating the urine of cows which have been fed on mango leaves (Bengal). To obtain euxanthone from the pigment it is exhausted with water, then with dilute hydrochloric acid, and the residue extracted with ammonium carbonate. From the ammonium salt hydrochloric acid precipitates euxanthic acid, which on hydrolysis with dilute sulphuric acid yields euxanthone and glycuronic acid.

Xanthoproteic Reaction (*Chem.*) A test for proteid substances depending on the production of a yellow colour when the substance is heated with strong nitric acid (the reaction may occur without heating) which is intensified on addition of ammonia. The colour depends on the formation of aromatic nitro-compounds such as picric acid. A common instance of the test is seen when nitric acid gets on to the hands.

Xanthorrhea (*Botany*). A genus of the *Liliaceæ*. *X. hastilis*, the Australian grass tree, yields a resin used in the manufacture of sealing wax and varnish.

Xanthosiderite (*Min.*) Hydrous ferric oxide, $Fe_2O_3 . 2H_2O$, containing 57 per cent. iron. It occurs usually in fibrous masses of a yellow brown colour. From the Harz, Ireland, etc.

Xe (*Chem.*) The symbol for XENON (*q.v.*)

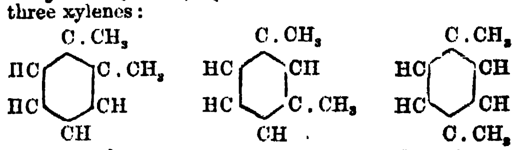
Xenon (*Chem.*) Xe. Atomic weight, 128. A colourless gas; boils at − 109°; it is a solid at the temperature of liquid air; has a monatomic molecule; no reactions. It occurs to the extent of about 1 volume in 20,000,000 volumes of air, and is obtained from the less volatile portion of liquid air (after removing the remaining oxygen and nitrogen) by fractional distillation. It has a characteristic spectrum containing many green lines.

Xerophyte (*Botany*). A plant modified for reduction of transpiration, owing to conditions in the soil preventing the normal absorption of water by the roots. Xerophytes are characterised by leathery leaves, thick cuticle, sunken stomata, etc.

Xoanon (*Archæol.*) The term applied to a primitive kind of statue, supposed to be the result of superhuman work, and revered accordingly.

Xylem (*Botany*). The term applied to the wood of plants. It consists of wood vessels and tracheides—two forms of water-conducting tissue—and a variable amount of wood fibres for support. *Cf.* PHLOEM.

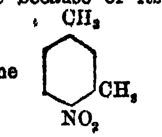
Xylenes (*Chem.*) (Dimethylbenzenes). There are three xylenes :



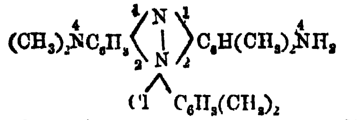
Orthoxylene.	Metaxylene.	Paraxylene.
M.P. − 28°	M.P. − 54°	M.P. + 15°
B.P. 142°	B.P. 139°	B.P. 138°

They all occur in coal tar, but metaxylene to a far greater extent than the others; thus commercial xylene from coal tar contains from 70 to 87 per cent. metaxylene. They can all be obtained by the general methods for obtaining benzene homologues, *viz.* (1) Fittig's reaction (*q.v.*); (2) Friedel and Craft's reaction (*q.v.*); (3) by distilling the sodium salts of suitable carboxylic acids with soda lime, *e.g.* metaxylene from mesitylenic acid. *See* MESITYLENE. They are all colourless liquids, smelling like benzene; insoluble in water. When boiled with dilute nitric acid the orthoxylene yields orthotoluic acid; the metaxylene is only slightly attacked; the paraxylene yields paratoluic acid. On further action of nitric acid the ortho- and para-compounds yield the corresponding dicarboxylic acids. Boiled with potassium permanganate they behave in the same way as with dilute nitric acid. Chromic acid oxidises orthoxylene completely to carbon dioxide and water, the other two to the corresponding dicar-

boxylic acids. The most important of the three xylenes is metaxylene, which can be separated from commercial xylene by boiling with diluted nitric acid, distilling the product in steam, shaking the distillate with caustic soda to remove acids, drying, and distilling over the metaxylene. Metaxylene is important because of its use in making dyes. A nitroxylene



can be prepared from it in the usual way. *See* NITRO-COMPOUNDS. This nitro-metaxylene on reduction (iron and hydrochloric acid) yields metaxylidine. Metaxylene also sulphonates like benzene, but it yields two isomeric sulphonic acids. Examples of dyes prepared with the use of xylene derivatives are: Methylene violet,



which is obtained by the action of nitrosodimethylaniline hydrochloride upon the hydrochloride of metaxylidine (and some paraxylidine). A number of scarlet dyes are derived from metaxylidine; *e.g.* Ponceau 2 R or Xylidine scarlet.

$$C_6H_3(CH_3)_2N \cdot \overset{1}{N} \cdot C_{10}H^4 \begin{cases} OH(2) \\ SO_2ONa(3) \\ SO_2ONa(6) \end{cases}$$

which is obtained by the action of β-naphtholdisulphonic acid R on a diazosalt of metaxylidine.

Xylidine (*Chem.*) *See* XYLENES.

Xylography. (1) Wood engraving: *see p.* 202; (2) Printing from engraved wood blocks.

Xylometer. An instrument for taking certain measurements in determining the specific gravity of woods.

Xylonite. A form of CELLULOID (*q.v.*)

Xylophone (*Music*). A musical instrument consisting of graduated blocks of resonant wood, which are struck by two small hammers.

Xylose (*Chem.*)

$$\begin{array}{c} CH_2OH \\ | \\ H.C.OH \\ | \\ HO.C.H \\ | \\ H.C.OH \\ | \\ CHO \end{array}$$

A five carbon atom sugar (pentose). Crystallises in white needles; melts about 145°; readily soluble in water and in hot alcohol; tastes sweet; is dextrorotatory and shows multi-rotation. On reduction it yields the corresponding alcohol, and on oxidation with bromine water it yields a monocarboxylic acid. On oxidation with nitric acid it yields a dicarboxylic acid—trioxyglutaric acid. It gives a tetra-acetate with acetic anhydride, and sodium acetate and an osazone with phenylhydrazine. Xylose does not undergo the alcoholic fermentation. It has been synthesised, and is known in the lævo- and inactive forms. Xylose is a splitting product of certain nucleo proteids, and so occurs in various organs of the body; it is also occasionally found in urine. It is a product of the hydrolysis of wood gum, but the wood gum need not be prepared first; thus it can be obtained from chopped wheat straw by first digesting with dilute ammonia, then hydrolysing with dilute sulphuric acid, and in a similar manner from brewery grains. *See also* SUGARS *and* OSAZONES.

Xyst *or* **Xystus** (*Architect.*) In classical architecture, a covered portico or other place in which athletes exercised.

Y (*Chem.*) The symbol for Yttrium (*q.v.*)

Y Level (*Surveying*). A level so called because the telescope is mounted on forked rests called "Y's," from which it can be lifted and reversed. A form of theodolite is called the "Y Theodolite" for a similar reason.

Y Theodolite (*Surveying*). *See* Y LEVEL.

Yak. A Tibetan species of ox (*Bos grunniens*), used as a beast of burden. The milk is of good quality, and the long silky hair is woven into ropes.

Yam (*Botany*). The plants of the genus *Dioscorea* (order, *Dioscoreaceæ*), are characterised by having large underground tubers of a starchy nature, used in the tropics for food.

Yarn (*Textile Manufac.*) A general term for the spun thread prepared for the weaver, either warp or weft. The yarn is defined as soft spun, medium spun, hard spun, according to the amount of twist it has received. *See* WARP *and* WEFT.

Yarn Counts (*Textile Manufac.*) The fixed length or weight for determining the counts, size, or diameter of a yarn. *See* COUNTS.

Yarn Testing (*Textile Manufac.*) Yarns are tested by special apparatus for twine, breaking strain, and elasticity.

Yaryan (*Paper Manufac.*) The term applied to an apparatus used for evaporating spent liquor to a small bulk.

Yataghan (*Arms*). A Turkish sword with the blade doubly curved, and the handle devoid of guard.

Yb (*Chem.*) The symbol for YTTERBIUM (*q.v.*)

Year, Civil (*Astron.*) A civil year consists of 365 mean solar days, except that every fourth year one extra day is added (Leap Year.) This extra day produces an error of over three days in 400 years, therefore in the Gregorian Calendar, three days are omitted every fourth century. The average length of the civil year then coincides very nearly with the Tropical Year. *See* YEAR, TROPICAL.

——, Sidereal (*Astron.*) The interval between two successive passages of the Sun through a point on the Ecliptic, determined by a reference to some Fixed Star.

——, Tropical (*Astron.*) The interval between two successive passages of the Sun through the First Point of Aries. The Tropical Year coincides with the seasons, but does not contain an exact number of days; its length is very nearly 365 days 6 hours. For this reason the Civil Year was devised. *See* YEAR, CIVIL.

Yeast. A fungus belonging to the genus *Saccharomyces*. There are several forms, such as BEER YEAST, seen only in a cultivated form; and WINE

YEAST, occurring in the soil of vineyards. The plant consists of minute organised cells containing granular matter. The cells at a certain temperature multiply enormously by budding, and cause alcoholic fermentation.

Yellow. *See* COLOURS, PRIMARY.

Yellow, Chrome. *See* CHROME YELLOW.

——, Indian. *See* INDIAN YELLOW.

Yellow Jasmine (*Botany*). A North American plant, *Gelsemium nitidum* (*Loganiaceæ*) (*not the cultivated jasmine*), used in pharmacy as a nervine and febrifuge in the form of an alcoholic extractive (Gelsemin) and an alkaloid (Gelsemina).

Yellow Ochre (*Chem.*) An impure ferric oxide.

—— (*Min.*) A variety of Limonite (*q.v.*) used as a pigment. From Pary's Mine, Anglesea, and Saddleback in Cumberland, etc.

Yellow Prussiate of Potash (*Chem.*) A common name for potassium ferrocyanide. *See* POTASSIUM COMPOUNDS

Yellow Topaz (*Min.*) A synonym for Citrine, a clear yellow variety of Quartz (*q.v.*) *See also* PRECIOUS STONES, *p.* 539.

Yellow Wove (*Print*) A technical anomaly. It is really a blue wove paper of a cheap kind.

Yenite (*Min.*) A synonym for LIEVRITE (*q.v.*)

Yew. *See* WOODS.

Yield Point (*Eng., etc.*) When a specimen is tested in the testing machine, a sudden increase of length usually occurs when the stress reaches a certain value. The point at which this occurs is termed the YIELD POINT.

Ylang-ylang. This perfume, also known as Macassar oil, is obtained from the flowers of a Malayan tree, *Cananga odorata* (order, *Anonaceæ*)

Yoke (*Elect. Eng*) The iron portion connecting the limbs of an electro magnet.

Yolk (*Woollen and Worsted Manufac*) The actual fat, or Suint (*q.v.*), of the wool fibre. The fine wools, such as merino, may contain 50 up to 60 per cent. of fatty matter; wools of the crossbred type contain a much smaller percentage.

Yorkshire Light (*Carp. and Join*) A solid frame with one sash sliding horizontally

Young Fustic. *See* DYES AND DYEING.

Ytterbium (*Chem*) Yb. Atomic weight, 173. A very rare metal occurring in gadolinite and euxenite. It forms an oxide, Yb_2O_3, and a sulphate, $Yb_2(SO_4)_3 8H_2O$ The metal has a characteristic spark spectrum.

Yttrium (*Chem*) Yt. Atomic weight, 89 A rare metal occurring in gadolinite, samarskite, and yttrotantalite. Its separation is a long and tedious process. It forms an oxide, Yt_2O_3, and a chloride, $YtCl_3$. The oxide glows strongly when heated. The metal has a characteristic spark spectrum.

Yttrocerite (*Min.*) A fluoride of calcium with cerium and yttrium metals. Massive. It contains cerium, yttrium, lanthanum, didymium, and erbium. From near Falun in Sweden and in North America.

Yttrotantalite (*Min.*) A tantalate and niobate of iron, calcium, yttrium, erbium, and cerium; orthorhombic. Colour black or brown. Tungsten, tin, and uranium are also sometimes present. From Sweden.

Yucca (*Botany*). A well known genus of the order *Liliaceæ*, native to North and Central America. A fibre of considerable value is obtained from several species.

Zaratite (*Min.*) A synonym for EMERALD NICKEL (*q.v.*)

Zedoary (*Botany*). A perfume and tonic obtained from the tubers of *Curcuma zedoaria* (*Zingiberaceæ*), a native of India and China.

Zeeman Effect (*Phys.*) An alteration in spectral lines produced by subjecting the source of light (which may be a flame, vacuum tube, etc.) to the action of a powerful magnetic field. When the light is viewed at right angles to the lines of force, each line becomes a triplet, the middle component having the same wave length as the original line. All the lines are plane polarised, but the plane of polarisation of the central line is perpendicular to that of the outer lines. When the light is viewed along the lines of force, instead of a triplet, a doublet with circularly and oppositely polarised components is produced. These are the simplest forms deduced from the theory, and are often actually obtained, but other modifications occur, and all lines do not behave alike, some being practically unaffected. Often a further splitting up of the components takes place. For instance, one of the yellow D lines is resolved into four and the other into six constituents, and in other cases the effect is still more complicated.

Zeisel's Process (*Chem.*) A method for determining the presence and number of the groups —OR in an organic compound where R is a hydrocarbon residue of the paraffin series. Such compounds are converted by the action of concentrated hydriodic acid into hydroxy compounds, while the alkyl group is converted into iodide. *Eg.* (1)

$$\underset{\text{(Anisol)}}{C_6H_5OCH_3} + HI = \underset{\text{Phenol.}}{C_6H_5OH} + CH_3I$$

(2) Quinine contains a methoxy (OCH_3) group. (3) Codeine contains a methoxy group The substance to be examined is weighed and placed in a small flask provided with a doubly bored cork; through one opening passes a tube through which carbon dioxide is led through the apparatus, while the tube of a reflux condenser worked with warmed water passes through the other opening of the cork. To the upper end of the condenser is attached a set of potash bulbs containing water and a little red phosphorus, the bulbs are immersed in water at 50° to 60°. The potash bulbs communicate with a flask containing a solution of silver nitrate in aqueous alcohol, to which a drop or so of nitric acid has been added—usually one flask is sufficient, but a guard flask containing only aqueous silver nitrate can be added if desired. Hydriodic acid is added to the substance, and the flask is brought slowly to boiling; any hydriodic acid or iodine escaping is stopped in the potash bulbs. Methyl iodide is kept gaseous by the suitably warmed water of the condenser and potash bulbs till it reaches the alcoholic aqueous silver nitrate, where it reacts to form a double compound of silver iodide and nitrate, which is decomposed by warming on the water bath with much water and a little nitric acid. The silver iodide is weighed. The method is not applicable

without modification to compounds containing sulphur. Zeisel's method can be used to determine alcohol of crystallisation, methoxy and ethoxy groups in such compounds as acetals; and a simple modification of it serves to determine alkyl groups attached to nitrogen (methylimide groups).

Zenith (*Astron.*) The direction of a point immediately over the head of the observer. The vertical point of the heavens at any place, and consequently the opposite of NADIR (*q.v.*)

Zenith Distance (*Astron.*) The angular distance of a star from the zenith (*q.v.*) It is the complement of the altitude.

Zenith Sector (*Astron.*) An astronomical instrument consisting essentially of a portion of a graduated circle, used for accurately measuring the zenith distances (*q.v.*) of stars which pass near the meridian; also in trigonometrical surveys for finding the difference in latitude of two stations by observing the difference in the zenith distances of a particular star at the two places as it passes the meridian.

Zenith Telescope (*Astron.*) A telescope, having adjustments in altitude and azimuth, used for observing the meridian passage or transit of two stars near the zenith, one north and the other south of the zenith.

Zeolite (*Min.*) Hydrous silicates of alumina and the alkalies; they are commonly found in lavas, and occasionally in other eruptive rocks.

Zephyr (*Textiles*). A light cloth composed of fine coloured yarns, with fine sett. Woven in plain weave in either stripe or check patterns.

Zero Method (*Phys., Elect. Eng., etc.*) A method of testing in which two quantities are adjusted till they are equal; the attainment of such equality is known by the absence of any effect in an indicating instrument, *e.g.* the absence of deflection in a galvanometer used with the Wheatstone Bridge (*q.v.*)

Zeuner's Valve Diagram (*Eng.*) A diagram used in the investigation of the action of a slide valve (*q.v.*) It consists of a circle whose diameter represents the travel of the valve; two smaller circles are drawn with their centres on a diameter of the larger circle, so as to touch the latter and also each other. The displacement of the valve, the steam opening, exhaust opening, etc., can be obtained by drawing radii of the larger circle corresponding to any given position of the crank, *i.e.* at any point in the stroke of the piston.

Ziervogel Process (*Chem.*) A process for extracting silver from silver-containing copper ores or mattes. It consists of a very skilful process of roasting the material, so as to expel arsenic and antimony and a part of the sulphur. The sulphides of the charge are converted, at any rate in part, into sulphates, which are again decomposed as the temperature of the furnace is raised, except the silver sulphate. The charge is withdrawn from the furnace when the temperature approaches that at which the sulphate is decomposed. The roasted product is extracted with hot water, and the silver is precipitated from the clear solution by copper. For some extremely interesting remarks on the complexity of the process see *An Introduction to the Study of Metallurgy*, by SIR W. C. Roberts-Austen, 3rd ed. pp. 8 *et seq.*

Zigzag (*Architect.*) A form of ornament in Norman work, also termed CHEVRON (*q.v.*)

Zigzags (*Textile Manufac.*) Designs in which the twill or diagonal runs alternately to the right and left.

Zinc (*Chem.*) Zn. Atomic weight, 65·4. A white metal with faint bluish tinge; melts at 419°; boils at about 920°. The vapour density shows zinc to have a monatomic molecule. The specific gravity of the metal is 6·9, and is raised somewhat by rolling. It is most ductile and malleable between 100° and 150°, while over 200° it becomes so brittle that it can be powdered. In the air the metal becomes superficially coated with carbonate, and then undergoes no further change. When strongly heated in air it burns with a bluish white flame to the oxide. Zinc decomposes water at a red heat, but if it is impure decomposition occurs even at 100°. Hot solutions of caustic soda or potash dissolve zinc slowly, forming zincates, $Zn + 2NaOH = Na_2ZnO_2 + H_2$. Dilute sulphuric and hydrochloric acids attack zinc, but extremely slowly. If impurities are present, as in commercial zinc, which contains carbon and iron, they attack it very readily, yielding a salt and hydrogen. Hot, strong sulphuric acid acts as an oxidising agent forming the sulphate, and is reduced to sulphur dioxide and in part even to sulphuretted hydrogen. Nitric acid attacks zinc readily, forming the nitrate and various reduction products of nitric acid, such as nitrogen, ammonia, nitrous oxide, and nitric oxide. Zinc throws out many metals from solutions of their salts, *e.g.* copper, tin, lead, mercury, cadmium, silver, and gold. It is often used as a reducing agent, alone in the form of zinc dust or with an acid or alkali; for example (1) many phenols are deprived of oxygen when heated with zinc dust, ordinary phenol giving benzene, alizarine giving anthracene; (2) succinimide gives pyrrole (*see* p. 582); (3) zinc and dilute sulphuric acid reduce ferric to ferrous salts, zinc and ammonia reduce copper acetylide to ethylene; (4) coated with copper (by putting clean zinc into 3 per cent. copper sulphate solution) it forms the zinc copper couple which is often used in effecting reductions, as for example the reduction of a nitrate to ammonia, or methyl iodide to methane. Zinc occurs naturally in the form of sulphide (zincblende, ZnS), carbonate (calamine, *q.v.*), silicate (siliceous calamine, $Zn_2SiO_4 . H_2O$). To obtain the metal the ore is roasted so as to form oxide, and the oxide, intimately mixed with powdered coal, is distilled in clay retorts—a part of the metal condenses as dust. Numerous electrolytic methods for obtaining zinc have been patented, but none has yet entered into serious competition with the distillation method. Pure zinc can be prepared from ordinary commercial pure zinc by distilling it in hard glass tubes in a vacuum. Zinc is used in making galvanised iron (*q.v.*); in making many important alloys, such as brass, bronze, and German silver; as the negative pole in a number of important cells (*see* CELLS); in the extraction of gold (*q.v.*)

Zinc Alkyls (*Chem.*) *See* ZINC COMPOUNDS.

Zinc Blende (*Min.*) *See* BLENDE.

Zinc Compounds (*Chem.*) ZINC OXIDE, ZnO, is a white powder; melting point unknown. Does not melt in the oxyhydrogen flame, and volatilises in the electric furnace. Can be obtained crystalline by strongly heating in oxygen. Occurs to some extent naturally in crystalline form. Very slightly soluble in water (about 2×10^{-4} gram molecules per litre); readily soluble in acids forming corresponding salts, and in caustic soda or potash forming zincates.

When heated it turns yellow, but becomes white again on cooling. It is reduced to the metal by heating it with carbon, or in a current of hydrogen (at 450°). It may be prepared by heating the metal in air, or by heating the hydroxide, carbonate, or nitrate. On the large scale it is made by the first of these methods. Zinc oxide is largely used as a paint (zinc white); it is also much used in medicine as an ointment or alone (astringent). The hydroxide $Zn(OH)_2$ is a white solid nearly insoluble in water; soluble in acids forming zinc salts, in caustic soda or potash forming zincates, and in ammonia forming complex zinc ammonia compounds. When heated it loses water and forms the oxide. It is obtained by precipitating a solution of a zinc salt with caustic soda or potash or ammonia solutions. The precipitant must not be in excess; it can be obtained in crystals by placing zinc in contact with copper or iron in ammonia. The zincates, for example, K_2ZnO_2, are obtained in the ways mentioned above and under Zinc; they are completely hydrolysed in dilute solution. ZINC CHLORIDE, $ZnCl_2$, is a white solid usually met with in sticks which have been cast; melts about 290°; boils at 730°. It has a normal vapour density. Zinc chloride is very deliquescent, and is used as a dehydrating agent; thus it is used in the preparation of alkyl chlorides (*see* Ethyl Chloride). It is very soluble in water (1 gram molecule in 2 of water at 15°), in alcohol, glycerine, and many other organic solvents forming compounds with them. Fused zinc chloride readily dissolves zinc oxide, and the solution sets to a hard mass. An aqueous solution of zinc chloride also dissolves the oxide, and a strong solution of this kind is used in dissolving silk. Zinc chloride combines with ammonia to form several compounds, *e.g.* $ZnCl_2.NH_3$ and $ZnCl_2 2NH_3$. Both these are very stable, and are obtained by direct union of their components. The $ZnCl_2 2NH_3$ is found in Leclanché cells. This power of zinc chloride to unite with ammonia is made use of in chemistry. *See* HYDRAZONES *and* SKATOLE. Alkaline chlorides unite with zinc chloride to form double salts, *e.g.* $(NH_4)_2ZnCl_4$. A solution of this salt is used in soldering. Zinc chloride may be prepared by dissolving the metal, oxide, or carbonate in hydrochloric acid and evaporating. During the evaporation basic chlorides of uncertain composition are formed, and these must be removed by addition of concentrated hydrochloric acid, or, better, by passing hydrochloric acid gas into the liquid during the process. Zinc chloride is used in medicine as a caustic, in solution as an antiseptic under the name Burnett's Fluid (*q.v.*), and on a large scale in weighting or filling textile fabrics—4 to 5 per cent. of it has been found in such fabrics. ZINC SULPHATE, $ZnSO_4$, is a white solid obtained by heating its heptahydrate at 100° to form the monohydrate, which is then heated over 240°. It is only decomposed at a white heat; but it is easily decomposed by heating with reducing agents, *e.g.* with carbon it is reduced to oxide or to zinc according to the temperature employed. Zinc sulphate is ordinarily met with as heptahydrate, $ZnSO_4 7H_2O$, commonly called white vitriol. This salt is formed by dissolving the metal, oxide, or carbonate in dilute sulphuric acid, and crystallising the solution. On the large scale the sulphide is roasted in such a way as to form sulphate which is extracted with water. When the solution is crystallised over 50° a hexahydrate is produced; the monohydrate is obtained as above. Zinc sulphate is very soluble in water (51 grs. in 100 grs. water at 15°). With the alkali sulphates it forms double salts, such as $K_2SO_4ZnSO_46H_2O$. It is used in medicine as an emetic and as a lotion, in dyeing and calico printing, and in the preparation of other zinc compounds. ZINC CARBONATE, $ZnCO_3$: The natural form is crystalline (*see* Calamine). Artificially prepared, it is a white powder very slightly soluble in water, more soluble in water containing carbon dioxide; easily decomposed by heat, $ZnCO_3 = ZnO + CO_2$. It is obtained by precipitating a solution of a zinc salt with acid potassium carbonate. When a normal carbonate is used, partial hydrolysis results, and basic carbonates of varying composition are obtained. It is used in medicine like the oxide. ZINC SULPHIDE, ZnS: The natural form (*see* BLENDE) is crystalline. That form known as Sidot's hexagonal blende (Würtzite) is strongly phosphorescent in the *a*-rays of radioactive elements. It is the most important ore of zinc. The artificial form is usually met with as a white powder; but it can be obtained crystalline by heating it to bright redness in a current of hydrogen or by heating zinc oxide in a current of sulphuretted hydrogen. It is very slightly soluble in water and in acetic acid, but readily soluble in mineral acids even when very dilute. Heated in air it forms either the sulphate or oxide; when heated with an oxidising agent, such as sodium peroxide, it forms the sulphate. It is obtained by precipitating a zinc salt with sulphuretted hydrogen or with an alkaline sulphide. In the former case precipitation will be incomplete if the acid liberated is a strong acid, such as sulphuric or hydrochloric; but it will be complete if it is a weak acid, such as acetic. Thus half the zinc is precipitated from a solution of 1 gram of zinc sulphate in 77 grams of water on saturating the solution with sulphuretted hydrogen. In the latter case precipitation is complete. To make the precipitation complete in the case of zinc sulphate it is only necessary to add excess of sodium acetate, so that the strongly ionised sulphuric acid is replaced by the slightly ionised acetic acid:

$$ZnSO_4 + 2NaC_2H_3O_2 + H_2S = Na_2SO_4 + 2C_2H_4O_2 + ZnS.$$

Zinc combines with alkyl groups to form the ZINC ALKYLS. A typical example of these compounds is zinc methyl, $Zn(CH_3)_2$, a colourless liquid which boils at 46°; has an unpleasant and dangerous smell; takes fire, burning with the zinc flame, instantly in air, but if dry air is allowed slow access to it, it forms a kind of peroxide, probably $Zn\langle{}^{O-O-CH_3}_{CH_3}$, which is explosive and liberates iodine from potassium iodide. It is decomposed by water and methyl alcohol as follows:

$$Zn\langle{}^{CH_3}_{CH_3} + {}^{HOH}_{HOH} = Zn\langle{}^{OH}_{OH} + 2CH_4$$

$$Zn\langle{}^{CH_3}_{CH_3} + {}^{HOCH_3}_{HOCH_3} = Zn\langle{}^{OCH_3}_{OCH_3} + 2CH_4$$

With alkyl iodides it yields, on heating, paraffins, $Zn(CH_3)_2 + 2ICH_3 = ZnI_2 + 2C_2H_6$. For its reactions with acid chlorides, aldehydes, and ethyl formate, *see* KETONES, SECONDARY ALCOHOLS, *and* TERTIARY ALCOHOLS. For another kind of reaction, *see* TIN COMPOUNDS. Zinc methyl combines with ether forming $2Zn(CH_3)_2(C_2H_5)_2O$. It is prepared by gently warming a dry zinc copper couple (washed with alcohol, then ether, and the latter removed by a current of dry hydrogen) with methyl iodide. Zinc methyl iodide, $Zn\langle{}^{CH_3}_{I}$, is first formed, and yields the zinc methyl on distillation. The apparatus must be perfectly dry, and the whole operation carried

out in an atmosphere of carbon dioxide. Zinc ethyl and other zinc alkyls are prepared, and behave in a similar way to zinc methyl.

Zinc Copper Couple (*Chem.*) *See* ZINC.

Zincite (*Min.*) Red oxide of zinc, ZnO. Hexagonal, very perfect cleavage, usually found massive; deep red colour. Found in New Jersey, where it is an important ore of zinc.

Zinc Methyl (*Chem.*) *See* ZINC COMPOUNDS.

Zincography. The process of producing a design in relief on a zinc plate, for the purposes of printing. *See* PHOTO ENGRAVING, *p.* 524.

Zinc White (*Chem.*) *See* ZINC COMPOUNDS.

—— (*Dec.*) A valuable white pigment consisting wholly of oxide of zinc (*q.v.*) The term zinc white is sometimes applied to the group of white pigments which consist of zinc sulphide and zinc oxide, combined with a large proportion, say 69 per cent., of barium sulphate, of which Orr's Zinc White (*q.v.*) is an example.

Zingiberaceæ (*Botany*). A Dicotyledon order of economic importance. Well known plants of the order are GINGER (*Zingiber*), CARDAMOM (*Elettaria* and *Amomum*), and TURMERIC (*Curcuma*).

Zircon (*Min.*) An oxide of zirconium, ZrO_2SiO_2; tetragonal. Colourless, grey, green, or brownish. Found in certain metamorphic and eruptive rocks, and also in alluvial deposits. The varieties Jargoon and Hyacinth (*q.v.*) are used as gems.

Zirconite (*Min.*) A grey or brown variety of ZIRCON (*q.v.*)

Zirconium (*Chem.*) Zr. Atomic weight, 90·6. A rare metal occurring in Series 6, Group IV. of the Periodic System (*q.v.*) It forms bright grey plates; melts about 1300°, only oxidised at a very high temperature. It is obtained from the dioxide by heating with carbon in the electric furnace, when a product containing carbon is obtained, which must be again heated with more oxide to free it from carbon. The metal forms a dioxide, ZrO_2, a tetrachloride, $ZrCl_4$, a silicate, $ZrSiO_4$. The silicate is the form in which zirconium is found naturally; it is called Zircon (*q.v.*) *See* JARGOON, HYACINTH, PRECIOUS STONES.

Zither (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 429.

Zizania (*Botany*). A genus of grasses. CANADA RICE (*Z. aquatica*) is used as a cereal in North America.

Zizyphus (*Botany*). A genus of shrubs or trees of the order *Rhamnaceæ*, mostly native to tropical Asia and America. *Z. chloroxylon* yields cogwood, *Z. Lotus* an edible fruit, *Z. vulgaris* the fruit known as French jujubes, and *Z. Joazeiro* a Brazilian fodder plant.

Zn (*Chem.*) The symbol for Zinc (*q.v.*)

Zocle (*Architect.*) *See* SOCLE.

Zodiac (*Astron.*) A imaginary belt or zone in the heavens, within which the motions of the sun, moon, and planets are confined. It extends about 8 degrees on each side of the Ecliptic (*q.v.*), and was divided by the ancients into twelve parts, each distinguished by a constellation, termed the Signs of the Zodiac.

Zodiacal Light (*Astron.*) A faint pyramid of light extending from the sun both east and west along the ecliptic. Best seen in northern latitudes in the evening in February and March, and in the morning in October and November.

Zoisite (*Min.*) A silicate of iron aluminium and calcium; orthorhombic, usually in radiating groups or crystalline masses; pink to brown or grey. Found in metamorphic rocks.

Zondas (*Meteorol.*) Northerly hot winds of the South American pampas.

Zone Axis (*Min.*) An axis in a crystal which is parallel to a set of crystal planes.

Zone Plane (*Min.*) A plane normal to the Zone Axis (*q.v.*)

Zoophorus (*Architect.*) The frieze of an entablature, particularly when carved with representations of animals. *See* FRIEZE.

Zostera (*Botany*). A genus of *Potamogetonaceæ* known in Britain as "grass wrack." The plants grow in salt water on sandy shores. When dried Zostera is much used as a packing material.

Zr (*Chem.*) The symbol for ZIRCONIUM (*q.v.*)

Zymase (*Chem.*) An enzyme extracted from yeast. Nothing is known with certainty as to its chemical composition, much less as to its constitution; perhaps it is a proteid. It is obtained from yeast by expelling water by pressing it at a pressure of 50 atmospheres, rubbing the pressed mass with the finest quartz sand and kieselguhr in order to destroy the cell walls, then again pressing, first by itself, then with a little water at 500 atmospheres. The expressed juice is filtered, and contains the enzyme, along with other enzymes of a different kind, such as proteolytic and peptic. The enzyme can be precipitated from the solution by alcohol ether (2:1); when washed with alcohol and ether and dried in a vacuum over sulphuric acid, it consists of a white mass which contains the enzyme, but is far from being pure. The importance of zymase lies in its property of fermenting glucose to alcohol and carbon dioxide; it also ferments lævulose, raffinose is more slowly fermented, galactose and glycogen still more slowly, lactose and arabinose not at all. *See also* ENZYMES. Its optimum conditions for glucose are temperature 22°, concentration about 16 per cent. glucose. Acids affect its action prejudicially; alkalis in small amount promote its action. Hydrocyanic acid stops its action altogether, but the activity is recovered by passing air through the liquid for a long time.

APPENDIX

Absorption Bands (*Phys.*) *See* SPECTRUM ANALYSIS, *p.* 698.

Acetate (*Chem.*) A salt of ACETIC ACID (*q.v.*)

Acid Drip (*Chem. Eng.*) *See* DRIP, *p.* 175.

Acid Egg (*Chem. Eng.*) *See* MONTEJUS.

Acid Pump (*Chem.*) *Add to definition on p.* 5: It is sometimes operated by compressed air instead of by a piston.

Actinism (*Phys.*) The special property of radiant energy, whether luminous or not, whereby chemical changes are produced. The production of such changes.

Actinometer (*Phys.*) An instrument (1) for measuring the heat intensity of the sun's rays; (2) for ascertaining the actinic effect of light rays.

Adipocere. A light-coloured fatty substance formed by the decomposition of animal tissues under moist conditions, but removed from atmospheric air.

Aldine Edition. The term signifies a book printed at the Aldine Press in Venice by Aldus Manutius or one of his family (1494—1597). Aldine editions are celebrated for their fine typography. The term Aldine is applied, in a modern sense, to a series of books in the same style; also to a display type. *Cf.* ELZEVIER *and* BLACK LETTER.

Algraphy. *See* LITHOGRAPHY, *p.* 362.

Alignment (*Typog.*) Uniformity in the base line of printing types.

Angle of Lag (*Phys.*) *See* LAG AND LEAD.

Anode (*Elect*). The conductor by which an electric current enters. *Cf.* CATHODE, *p.* 92.

Aphelion (*Astron.*) That point, in the orbit of a planet or a comet, which is most distant from the sun. [To precede wording of definition on p. 22.]

Aplanatic (*Optics*). The term is applied to an object-glass, or a combination of lenses, which bring parallel rays to a focus without spherical or chromatic aberration.

Apochromatic (*Optics*). The term applied to a lens constructed so as to correct spherical and chromatic aberration to a greater extent than in an ordinary object-glass. *See* ACHROMATIC LENS *and* ACHROMATISM, *p.* 4.

Apogee (*Astron.*) The point, in the orbit of a planet or other heavenly body, which is farthest from the earth; the term relates especially to that point in the moon's orbit. [To precede wording of definition on p. 22.]

Artificial Silk. *See* WOOD PULP.

Ballistic Galvanometer. *See* GALVANOMETERS, *p.* 246.

Basil (*Leather*). Bark-tanned sheep skin, used for binding, etc. *Cf.* ROAN.

Batter (*Eng.*) The backward slope or inclination, from the base, of a wall, embankment, or the sides of a railway cutting. This gives resistance to the "thrust," and ensures greater stability.

Baumé Scale. *See* HYDROMETER SCALES.

Beck (*Textiles*). A vessel for holding dye liquor, etc.; also termed a BACK.

Beck's Scale. *See* HYDROMETER SCALES, *p.* 298.

Beer. To the list of adulterants, *add* Cocculus Indicus (*q.v.*)

Bench (*Gas Manufac.*) The term applied to a set of retorts used for the dry distillation of coal.

Benzine (*Chem. Tech.*) A popular term, not used in exact chemical nomenclature. Sometimes applied to a mixture of commercial benzenes; also to a light petroleum distillate better known as Benzoline, which is quite a different substance chemically. *See* BENZENE, *p.* 49.

Billets (*Met.*) Short lengths of square bars (blooms) of iron or steel fed to the roughing rolls of a mill for conversion into light sections of merchant iron or rails. *Cf.* PILES.

Black Plates (*Met.*) The name given to sheet iron intended for tinplates, before it is tinned.

Black Tin (*Met.*) The term applied to comparatively pure tin ore, *i.e.* ore which has been subjected to various dressings.

Block Tin (*Met.*) Add to definition on p. 55: The term is also applied to articles (1) made entirely of tin, (2) made of tinplate (*q.v.*) of superior quality.

Bog Iron Ore (*Min.*) This is sometimes used for purifying coal gas. *See also p.* 57.

Bottom (*Mining*). The floor or bed rock on which a coal seam lies.

Bottoms (*Chem. Tech.*) (1) A general term for impure residues, *e.g.* caustic soda bottoms. (2) The term applied to colours which serve as a foundation for other colours in dyeing fabrics.

Bow (*Music*). *See* MUSICAL INSTRUMENTS, *p.* 427.

Broach (*Tapestry Manufac.*) The needle or small spindle used for inserting the weft.

—— (*Tools*). (1) A stonemason's chisel, with narrow point. (2) A kind of gimlet or bit used for boring a cask.

Bucking Kier (*Linen Manufac.*) A vessel in which linen cloth is boiled with lime water in the first process of bleaching.

Burr. This term is applied to various tools used for abrading or drilling purposes, *e.g.* a fluted reamer; to a mortising chisel of rectangular section; to a blank punched from a sheet of metal.

Burrstone *or* **Burrh** (*Min.*) A silicious rock which is dressed and used for millstones.

Cadency (*Her.*) *See* LABEL, *p.* 334.

Cal., cal. An abbreviation of CALORIE (*q.v.*, p. 81). *See also* UNITS.

Camp Sheathing, Camp Sheet, Camp Shed (*Civil Eng.*) A plank structure placed at the foot of a sloping embankment or soft cutting to resist the thrust or prevent the soil from washing away.

Canopic Vase (*Archæol.*) A vase of peculiar shape, used by the Egyptians as a receptacle for a portion of the entrails of embalmed bodies, and by the Etruscans for holding the ashes of the dead. The lid represented a human head, the arms being sometimes added in the case of Etruscan vases, which were also provided with handles.

Carriage Gain (*Cotton Spinning*). *See* RATCHING.

Cartier's Scale. *See* HYDROMETER SCALES, *p.* 298.

Carton. A thin pasteboard used for making boxes. A box of this material.

Cementite (*Chem., Met.*) *See* IRON, *p.* 319.

Centroclinal Dip (*Geol.*) *See* QUAQUAVERSAL, *p.* 584.

Chemical Pulp. *See* WOOD PULP, *p.* 851.

Circumferentor. A small graduated wheel which revolves on a handle. Used for measuring the length of a wheel tyre.

Climate. *See* METEOROLOGY, *p.* 396.

Clump *or* **Clunch** (*Mining, etc.*) A coarse kind of clay. Specifically the compressed clay that occurs in coal strata.

Clumps (*Typog.*) Pieces of metal of same height as leads (*q.v.*) and cast to thickness of the bodies of type, usually nonpareil, brevier, long primer, and pica.

Clypeus (*Archæol.*) (1) A large circular shield, convex on the outer and concave on the inner side. *Cf.* SCUTUM *and* TARGE. (2) A sculptured representation of a shield hung in the intercolumniation of the atria in Roman buildings.

Collimation. (1) The accurate adjustment of the line of sight of a telescope, transit instrument, etc. (2) Bringing into line the axes of two lenses, or telescopes, which are then said to be "in collimation." (3) Determining or correcting the deviation of the line of sight of a telescope by means of a collimator. *Error of Collimation*: The deviation of the line of sight of a telescope from a plane at right angles to the axis on which it turns. This must be allowed for or corrected in observations. *Line of Collimation*: The correct line of sight or optical axis.

Collimator. (1) A subsidiary fixed telescope with fine wires or spider lines in its focus, used to determine or correct errors in collimation. (2) The tube of a spectroscope (*q.v.*) that carries the slit and contains lenses for rendering parallel the rays intended to fall on the grating or prism.

Collotype, Collodiotype (*Photo.*) A photograph made by a process (generally the wet process) in which the plate is coated with sensitised collodion. *See* WET PROCESS *under* PHOTO ENGRAVING, *p* 523, *and* PHOTOGRAPHY, *p.* 525.

Commensal (*Biol.*) An animal or plant that lives with another, as a tenant, but not at the expense of the host, *i.e.* it is not a true parasite (*q.v.*)

Continental Conditions (*Geol.*) The geological conditions prevailing in large land areas, remote from the sea; characterised by low rainfall, scarcity of rivers, presence of salt lakes, etc.

Conveyor (*Chem. Eng.*) An endless travelling belt; a chain carrying plates or trays; or a spiral worm in a trough; used for transporting solids. Certain types are called CREEPERS. ROCKERS take the form of a long trough (with cross ridges) to which a reciprocating motion is given. The aerial ropeway is a type of bucket conveyor, but of a different order to the usual form of conveyor. *Cf.* ELEVATOR.

Copy Holder (*Typog.*) A boy or girl who reads the "copy" or manuscript aloud while the Reader (*q.v.*) verifies the proof.

Cords (*Bind.*) *See* BANDS, *p.* 39.

Coumalic Acid (*Chem.*) *See* PYRONES, *p.* 578.

Coumalin (*Chem.*) *See* PYRONES, *p.* 578.

Cyanides. *See* GAS MANUFACTURE (C), *p.* 250.

Desmotrophy (*Chem.*) *See* TAUTOMERISM, *p.* 748.

Die Stock (*Eng.*) *See* STOCKS AND DIES, *p.* 723.

Downtonian Rocks (*Geol.*) *See* LUDLOW ROCKS, *p.* 368.

Drosser (*Glass Manufac.*) An iron frame used for separating the "tables" in glass making. *See* GLASS MANUFACTURE, *p.* 258.

Dust Destructor. A form of furnace in which house refuse, cinders, etc., are burnt. The material is first dried by exposure to the heat of the furnace, and then consumed under forced draught. *See also* WASTE PRODUCTS, *p.* 834.

Earth Colours (*Dec.*) A term sometimes applied to those colours or pigments which are found in nature, such as ochre, sienna, umber, etc.

Eutectic (*Met., etc.*) Fusing easily, *i.e.* at a low temperature. The term is applied to compound substances, *e.g.* alloys, the fusing point of which is lower than that of the constituents themselves. "The ratios in which metals unite to form the alloy possessing the lowest melting point are never atomic ratios, and when metals do unite in atomic ratios the alloy produced is never *Eutectic*. Metallic alloys are true homologues of the cryohydrates."—F. GUTHRIE in *Nature*.

Feeder (*Print.*) The person who feeds the sheets of paper into a printing machine—the "layer-on." The word also describes a mechanical contrivance for superseding hand labour in this operation.

Ferrite (*Chem., Met.*) *See* IRON, *p.* 319.

Figurine (*Art*). A small figure or a group of small figures made of various materials, *e.g.* metal, pottery; used for decorative purposes. *Cf.* TANAGRA FIGURINES, *p.* 743.

Fishing (*Eng., etc.*) (1) The operation of joining rails, etc., by means of fish plates. *See* FISHED JOINT *and* FISH PLATES, *p.* 223. (2) The removal of sulphate of ammonia crystals from the saturator. *See* GAS MANUFACTURE (C), *p.* 250.

Flot (*Geol.*) A northern English lead miners' name for certain lateral extensions of ore proceeding from a metalliferous vein into the country rock. Flots occur only in connection with those parts of the vein which consist of limestone.

Fob (*Soap Manufac.*) *See* FITTING, *p.* 223.

Funnel (*Chem.*, *etc.*) Generally a widemouthed conical apparatus, having a tube at the apex. Used for filling vessels with narrow openings, filtering, etc.

Fuse (*Elect. Eng.*) *See* SAFETY FUSE, *p.* 630.

Gas, Coal. *See* GAS MANUFACTURE, *p.* 248.

Geographical Mile. *See* WEIGHTS AND MEASURES, *p.* 843.

Glazed Pig (*Met.*) *See* BLAZED PIG, *p.* 54.

Gramaphone. *See* PHONOGRAPH, *p.* 520.

Gums. *See also* RESINS, *p.* 610.

Gyrostat (*Phys.*) An instrument used in experiments on the properties of rotating bodies, *e.g.* to show that the axis of a rotating body tends to retain its position in space, independent of any motion which may be given to its supports. It consists essentially of a heavy fly wheel whose axle is supported so that it can set itself in any direction.

Half-space Landing (*Build.*) *See* STAIRCASE, *p.* 707.

Halvans, Halvings, Hanaways (*Mining*). A Cornish term for ore refuse or inferior ore.

Hand Loom (*Weaving*). *See under* SILK, *p.* 673.

Hand Whip (*Mining*). A primitive contrivance consisting of a long pole, pivoted on a suitable support. A bucket for raising water, etc., is suspended from one end, and a counterbalance weight is attached to the other.

Hanging Wall (*Mining*). The upper "wall" or overhanging side of an inclined lode.

Hartshorn, Spirit of. *See* SPIRIT OF HARTSHORN, *p.* 703.

Heading Joints (*Carp.*) The joints between the ends of floor boards, *i.e.* at right angles to the edges.

Heading Side (*Mining*). The lower side of a lode.

Head Race (*Eng.*, *Mining*, *etc.*) The race or channel which conveys water to a water-wheel. *Cf.* TAIL RACE, *p.* 742.

Heave (*Mining*). A fault (*q.v.*) which raises a lode.

Hitch (*Mining*). A slight fault whose throw is less than the thickness of the seam or vein.

Hole (*Mining*). The expression "to hole" is used in various senses—*e.g.* (1) the making of an opening from one working, etc., to another; (2) undermining or undercutting so that the mineral may fall by pressure.

Horse (*Mining*). A mass of unprofitable material (country rock, etc.) separating two parts of a lode or seam.

Horse Fat. At one time horse fat was obtained from the neck only of the horse, and that fat is still more valued than fat from other parts of the body, as it is whiter and more solid. Neck fat is of the consistency of lard, except in very warm weather; while other horse fat is practically liquid, except in the winter. The two kinds of fat also differ in smell; and while the neck fat is a pure white, the other has a yellow colour, with a strong dirty brown tinge. The very best specimens of neck fat have no smell at all. Horse fat is usually mixed with bone grease, and it is difficult to get it pure. The average specific gravity of the neck fat is about 0·92. The fat of the kidneys, however, is nearly as heavy as the neck fat. In veterinary practice horse fat is employed as an ointment; but its main use is in soap manufacture, more particularly for soft soaps. Horse fat also finds a limited use for lubrication, as some practical men consider it best for certain classes of machinery. Harness makers use it for greasing leather, and wool combers use it locally where it is readily obtainable. The marrow of the horse is a yellow fat, solid at any ordinary temperature. It yields a very hard soap with caustic soda, but is very rarely used alone. Mixed with other fats, especially bone grease and cotton seed oil, it is used in soft soap manufacture. It presents no difficulties in working, and the amount of alkali required for saponification is about one-fifth of its own weight, which is about the average of fats generally, if we exclude cocoanut and palm kernel oil. These fats are used for the better classes of soap, and are never used with horse fat. Adulteration of horse fat with bone oil is best detected by determining the iodine number. This is 84 for horse fat, and never exceeds 70 for bone oil, being usually about 67. Hence any iodine value distinctly below 84 probably denotes adulteration with bone fat.

Hurdling (*Mining*). Passing ore through a coarse screen or sieve.

Hushing *or* **Hush** (*Mining*). Washing away the loose ground covering a vein lying near the surface by a sudden rush of water.

Hydraulic Mining, Hydraulicking. Working loose ore-bearing rocks (*e.g.* gravel containing gold) by a powerful jet of water.

Hygiene. The branch of medical science that deals with the preservation of health in regard to individuals and communities. *See* SANITATION, *p.* 635.

Incense. *See* THUS, *p.* 768.

Iserine (*Min.*) *See* ILMENITE, *p.* 302.

Kalpis (*Pot.*) *See* CALPIS, *p.* 82.

Kier (*Textiles*). A vat in which textiles are bleached. *Cf.* BECK *and* BUCKING KIER.

Kilo. *See* WEIGHTS AND MEASURES, *p.* 843.

Knot. Literally one of a series of knots placed at regular intervals in a log-line, the distance between two knots bearing the same relation to a mile as half a minute does to an hour, *i.e.* $\frac{1}{120}$. In common use, however, the term knot is employed as an equivalent for NAUTICAL MILE (*q.v.*) or for a speed of one nautical mile per hour. *See also under* WEIGHTS AND MEASURES, *p.* 843.

Lamella, *pl.* **Lamellæ.** The diminutive of Lamina. A thin plate or scale. *See p.* 340.

Lava (*Geol.*) A rock of volcanic origin which has solidified from a fluid mass at or near the surface. *See* ANDESITE, TRACHYTE, BASALT, RHYOLITE, etc.

Liquation, Eliquation (*Met.*) The process of heating ores or alloys in order to separate the metals, the one that has the lowest melting point being first obtained. The process is employed in refining tin.

Literals (*Typog.*) The mistakes of the compositors in single letters only, *viz.* the taking up a wrong letter or inverting a right letter.

Locking Stone *or* **Locking Pallet** (*Watches and Marine Chronometers*). The jewel fixed in the detent of a chronometer escapement for the purpose of arresting the advance of the escape wheel at the conclusion of every impulse. *See* DETENT, *p.* 156.

Lustra Cellulose (*Artificial Silk*). *See* CELLULOSE, *p.* 94, *and* WOOD PULP, *p.* 852.

Machining (*Print.*) The term used to express the operation of printing by machine. *Cf.* PRESSWORK.

Majuscule (*Palæography*). A capital or uncial letter; originally written separately, but later cursively—subsequently replaced by the new cursive, developed from the Minuscule (*q.v.*) *See also* UNCIAL, *p.* 809.

Marquetry (*Furniture*). Veneer of different woods forming a mosaic design.

Mechanical Pulp. *See* WOOD PULP, *p.* 851.

Mill (*Met.*) That department of an ironworks in which the blooms and rough bars from the "forge" (which has also shingling and rolling machinery) are piled, reheated, and rolled into merchantable iron.

Milling (*Chem. Eng.*) The process by which toilet soap is perfumed and prepared for the tablet dies. Thin chips of dried "stock" soaps are passed between granite rollers, travelling at different speeds, so that the soap is rubbed and squeezed together as well as crushed. Perfumes, etc., are generally incorporated during the milling.

Minuscule. (1) The cursive script hand developed from the semi-uncial between the 7th and the 9th centuries. It formed the basis of the small Greek and Roman letters of modern times. (2) A lower-case letter as opposed to an upper-case letter. *Cf.* MAJUSCULE (*and* UNCIAL, *p.* 809).

Modulator (*Music*). *See* TONIC SOL-FA, *p.* 777.

Möellon (*Chem. Eng.*) *See* SOD OILS, *p.* 689.

Moloxide (*Chem.*) *See* OXYGEN, *p.* 488.

Montejus (*Chem. Eng.*) The equivalent of an acid egg. A pistonless pump for raising acids, etc., by compressed air.

Morocco (*Leather Manufac.*) *See also* PERSIAN, *p.* 511, *and* ROAN, *p.* 618.

Mud Drum (*Eng.*) A cylinder attached by pipes to the lowest part of the boiler. It receives the feed water, and is supposed to allow the mud and sediment to settle out before the water rises into the boiler shell. Not in universal use, filtration of the feed water being much more effectual and safer, as unless protected from direct heat they are liable to burn and become dangerous. In tubular boilers they are sometimes provided as part of the design. The growing belief that a boiler is not a sludge tank but an evaporator is disposing of their use.

Nogging Pieces (*Carp*). The horizontal pieces of quartering fixed between the studs of a partition to stiffen it.

Oils. *See also* LUBRICANTS, *p.* 367.

Optics. The study of phenomena of light and vision, and of the various instruments employed in connection therewith.

Overblow (*Met.*) In the Basic steel process, after the carbon has been removed in the Bessemer converter, the "blow" is continued for another two or three minutes, during which the phosphorus in the charge is eliminated. Also called the AFTER-BLOW.

Peristaltic (*Elect.*) The term used by Lord Kelvin to describe the kind of electrostatic induction that occurs between conductors enclosed in the same insulator, *e.g.* in an ocean cable.

—— (*Physiol.*) The term applied to the wave-like and involuntary contractile muscular movements (peristalsis) of any hollow organ of the body, especially the alimentary canal, whereby the contents are propelled onwards.

Pole (*Silk Manufac.*) A term synonymous with pile, *e.g.* pole warp = pile warp. *See* PILE (*Textiles*), *p.* 532.

Pseudomerism (*Chem.*) *See* TAUTOMERISM, *p.* 748.

Raising Gig (*Woollen Manufac.*) A machine that raises a nap on cloth.

Red Prussiate. Another name for POTASSIUM FERRICYANIDE (*q v.*), p. 552.

Selective Absorption. *See* SPECTRUM ANALYSIS, *p.* 698.

Sienna (*Paint.*) *See* BURNT SIENNA, *p.* 77, *and* TERRA DI SIENNA, *p.* 759.

Soffit (*Build.*) The head-lining of a door or window opening. The underside of a flight of stairs or balcony, looking upwards.

Sparking Plug (*Motors, etc.*) A miniature arc lamp, between the terminals of which a low or high tension spark is passed by means of a current obtained from a storage battery or magneto machine. It is placed in the combustion chamber of an internal explosion motor to fire the gaseous fuel. The main conductor is insulated by embedding it in a plug of glass, porcelain, mica, or other fireproof insulating material. The plug and conductor are mounted in a brass or other metal screw collar or union which carries a wire terminal, bent to face the main conductor at the base of the plug. The points of the terminals can then be adjusted to leave a sparking "gap" of about $\frac{1}{16}$ inch.

Stall Board (*Carp.*) The boarding inside a shop window on which the goods are displayed.

Standard Cell (*Elect.*) A form of primary cell whose E.M.F. is accurately known and not liable to much variation. It is not used to produce a current, but as a standard of electromotive force for comparison with other electromotive forces, calibration of instruments, and similar processes requiring a standard.

Strata, Table of (*Geol.*) Stratified rocks are tabulated by the geologist according to age, which is determined by consideration of the fossils contained in the rocks, and by the physical relations of the different beds one to another. A number of beds are grouped together into SYSTEMS, *e.g.* the CARBONIFEROUS SYSTEM, which includes the various SERIES known as the Coal Measures, Millstone Grit, and Carboniferous Limestone Series. Each series is further classified according to the natural division into separate beds, which may vary in different places. The various Systems are further grouped together into PRIMARY, SECONDARY, TERTIARY and POST-TERTIARY, or QUATERNARY ROCKS; another set of rocks, older than any of the foregoing, are termed ARCHÆAN or PRE-CAMBRIAN (*see p.* 557).

With the advance of geological knowledge, modifications of the recognised classification continually occur. Thus there are reasons why the Dyas should be treated as Secondaries rather than as Primaries, and the method of division of the Cambrian, Ordovician, and Silurian Rocks is still the subject of much discussion. The classification most generally adopted is shown in the following table, which follows the method of Lapworth:

QUATERNARY *or* ANTHROPOZOIC.	POST-TERTIARY		Recent; Raised beaches, etc. Pleistocene *or* Glacial deposits	Most of the animals and plants at present existing.
TERIARY *or* CAINOZOIC.	TERTIARY	Upper	Pliocene: Norwich Crag, Red Crag, etc. Miocene: Absent in Britain	Plants and animals closely resembling those now living.
		Lower	Oligocene: Upper (absent in Britain); Hempstead Beds, etc.; Headon Beds Eocene: Bagshot Beds; London Clay; Lower London Tertiaries	
SECONDARY *or* MESOZOIC.	CRETACEOUS	Upper	Chalk Upper Greensand, Gault	Abundant animal life: the gigantic reptiles of the Jurassic Rocks occur, and a number of species of birds. Plant remains include those of the Jurassic system, with the addition of many higher forms. Thus in the Cretaceous Rocks of Germany, the Oak, Walnut, and Fig occur, and many additional species are found in America.
		Lower	Lower Greensand Wealden	
	JURASSIC	Upper	Portland and Purbeck Beds Kimmeridge Clay Corallian and Oxford Clay	Numerous fishes, reptiles (*Ichthyosaurus*, *Plesiosaurus*, *Dinosaurus*, and *Pterosaurus*), the earliest known bird (*Archæopteryx*), and certain marsupial Mammalia. Lower forms of animal life are numerous. Many plants occur, the most important being Cycads and Conifers.
		Middle	Great Oolite Inferior Oolite	
		Lower	Upper Lias Marlstone *or* Middle Lias Lower Lias	
	TRIAS	Keuper	Marls, Sandstones, etc.	Reptiles: Amphibia (*Labyrinthodonta*). Fishes: Crustacea (*Estheria*, etc.), Mollusca (*e.g.* *Ceratites*), Brachiopods (*Terebratula*, *Spirifer*). Certain plants, *e.g.* *Equisetum*, *Voltzia* (a Conifer), and Cycads.
		Muschelkalk	Shell limestone (Central Germany)	
		Bunter	Sandstones and Pebble Beds	

PRIMARY or PALÆOZOIC.	DYAS (Permian)	Magnesian Limestone, etc. Permian Sandstone	Corals, Bivalves, Fishes, Amphibians, and the first Reptiles (*Proterosaurus*).
	CARBONIFEROUS	Upper: Coal Measures (Upper Coal Measures; Main Coal Measures; Gannister); Millstone Grit Lower: Carboniferous Limestone Series (Yoredale Rocks; Mountain Limestone; Lower Limestone Shales)	Extensive plant remains, *e.g.* Ferns, Equisetum, and Lycopods (Club Mosses). Marine fossils, *e.g.* Corals, Echinoderms, Mollusca, Fishes, Amphibia (*Labyrinthodonta*).
	DEVONIAN (Old Red Sandstone)	Upper Pickwell and Petherwin Beds. Middle Ilfracombe Beds Lower Lynton Beds	Numerous characteristic Fishes: a certain amount of plant life (Sea-weeds and plants allied to the Equisetum and to the Tree Ferns), Brachiopods, and some Trilobites.
	SILURIAN	Upper *or* Downtonian Rocks Middle *or* Salopian (Ludlow, Wenlock) Lower *or* Valentian (Tarannon, etc.)	Numerous Trilobites, Mollusca, Graptolites, Corals; the earliest remains of land plants, and of Fishes.
	ORDOVICIAN	Upper *or* Caradoc Rocks Middle *or* Llandeilo Lower *or* Arenig	Graptolites are here the most important fossils. Trilobites are also common, as well as Brachiopods, and Cephalopods, Lamellibranchs, and Echinoderms occur.
	CAMBRIAN	Upper: Tremadoc Slates; Lingula Flags Lower: Menevian Group; Harlech Group	Trilobites are the most characteristic fossils. A number of Mollusca and Molluscoida (Brachiopods) are found; no Vertebrates or land animals.
ARCHÆAN.	PRE-CAMBRIAN ROCKS (*see* p. 557)		

Terne Plate (*Met.*) A kind of tinplate (*q.v.*), the coating of which consists of an alloy of lead and tin.

Turning Piece (*Build.*) A piece of timber cut to shape, to form a half-brick arch on.

Wale, Wale Piece (*Civil Eng.*) A piece of timber fastened horizontally to a row of piles, etc., to receive the impact of vessels. The horizontal part of a CAMP SHEATHING (*q.v.*)

CORRIGENDA

Agar-Agar. *For* Red Sea weeds *read* red sea-weeds.

Alcoholimetry (*Chem.*) *Read* **Alcoholometry.**

Allen's Governor. *For* value (last line) *read* valve.

Amorino. *Read* in architecture *after* often used.

Angle of Flexture (*Eng.*) *Read* **Angle of Flexure.**

Aperture (*Photo.*) The definition should read: The *diameter* of the "stop" or opening through which the beam of light *transmitted* by *a* lens must pass.

Aphelion (*Astron.*) *For* PERHELION *read* PERIHELION.

Apse *or* **Apsis** (*Astron.*) Substitute definition: The point of an eccentric orbit where the planet is either farthest from or nearest to the centre of attraction, termed respectively the higher apse and the lower apse. These terms are applied also to elliptic orbits. The apses of a planet are its APHELION (*q.v.*) and PERIHELION; those of the Moon its APOGEE and PERIGEE.

Archæology. *After* appertains to *read* man in.

Architecture, p. 25, line 25. *For* Erectheum *read* Erechtheum.

Armature (*Elect. Eng.*) *For* magnetic lens *read* magnetic lines.

Balance Wheel (*Clocks and Watches*). Refer to the definition under **Balance** (*Watches*), which is the modern term. *See also* **Balance Spring.**

Bands (*Bind.*) *For* in the back *read* on the back.

Baryto Calcite (*Min.*) *For* $BoCO_3$ *read* $BaCO_3$.

Batten Lay *or* **Lathe** (*Silk Manufac.*) *Read* **Batten, Lay** *or* **Lathe.**

Beam, p. 45, col. 2, line 12. *Read* co-efficient of elasticity (E).

Beer (line 10). *For* arsenic containing *read* arsenic-containing.

Bifilar Suspension (*Phys.*) *For* constant (8th line) *read* continuous.

Block Tin. *For* Refined Tin *read* Grain Tin.

Bone (*Zool.*) The word "calcium" should be repeated before carbonate and before fluoride. *For* cheifly *read* chiefly.

Calcium Compounds (*Chem.*), p. 81, line 21. *For* Gypsum, $CaSO_4 2H_2O$ *read* Gypsum, $CaSO_4 . 2H_2O$.

Candle. *After* during combustion (4th line from end) *read* and their low illuminating power.

Carbolic Acid. *For* so violent a poison (2nd line from end) *read* a violent irritant poison.

Caryatid (*Architect.*) *For* Erectheum *read* Erechtheum.

Cements (*Build.*) *For* solution of lime (5th line from end) *read* solution of alum.

Chronometer. *For* dedent *read* detent.

Circumferenter. *Read* **Circumferentor.**

Colours (*Pigments*), p. 119, 2nd column, line 8. *For* cadmium, *read* cadmium yellow.

Colours, Complementary. For (*Pigmeuts*) read (*Pigments*).

Cross (*Her.*) Fig. 1, legend line. *For* CLECHÉE *read* CLECHÉE FITCHÉE.

Declination (*Astron.*) *For* horizon *read* equator (p. 152).

Dressing (*Mining*). *For* TRUE VANNER *read* FRUE VANNER.

Engraving, p. 203. HOLLAND. *For* Rembrant *read* Rembrandt.

Fitting (*Soap Manufac.*) *For* NEST SOAP (4th line from end) *read* NEAT SOAP.

Gathering (*Bind.*) *For* volume from *read* volume form.

Gum Animé, p. 273. *For* **Animé** *read* **Animi.**

Musical Instruments, p. 427, line 16. *For* cymbals *read* cymbalo.

Opoponax, p. 477. *Read* **Opopanax.**

Overstep (*Geol.*) *Read* A stratum is said to *overstep* another . . . etc. (p. 483).

Paper, p. 496, line 29 from end. *For* stiff chests *read* stuff chests.

Pile (*Textile Manufac.*) *For* cut; or left in loop, *read* cut, or left in loops.

Ptomaines (*Chem.*), p. 569, line 14. *Read* substances obtained from corpses, which have basic properties, and show the general reactions of the plant alkaloids.

Pynknometer. *Read* **Pyknometer.**

Rhyolite (*Geol.*) *For* crumbling *read* crumpling.

Speed Gears, p. 699, col. 2, line 32. *For* sun *read* sum.

Tungsten (*Chem.*) *Read* Atomic weight 184.

Wall Rib, p. 832. *For* BIB *read* RIB.
